January 5, 2017:	**Payment date**—Dividend is paid to whoever owned the stock at closing the day prior to the ex-dividend date.

Therefore, if Buyer is to receive the dividend, she must buy the stock on or before December 12 and still own the stock on December 12. If she buys it on December 13 or later, Seller (who owned stock on December 12) will receive the dividend because he will be the official holder of record.

Katz's dividend amounts to $0.50, so the ex-dividend date is important. Barring fluctuations in the stock market, we would normally expect the price of a stock to drop by approximately the amount of the dividend on the ex-dividend date. Thus, if Katz closed at $30.50 on December 12, it would probably open at about $30 on December 13.

4. *Payment date*. The company actually pays the dividend on January 5, which is the **payment date**, to those owning the stock on December 12.

14-2b Stock Repurchase Procedures

Stock repurchases occur when a company buys some of its own outstanding stock.[3] Three situations can lead to stock repurchases. First, a company may decide to increase its leverage by issuing debt and using the proceeds to repurchase stock; we discuss

[3]The repurchased stock is called "treasury stock" and is shown as a negative value on the company's detailed balance sheet. On the consolidated balance sheet, treasury shares are deducted to find shares outstanding, and the price paid for the repurchased shares is deducted when determining common equity.

recapitalizations in more detail in Chapter 15. Second, many firms have given their employees stock options, and companies often repurchase their own stock to sell to employees when employees exercise the options. In this case, the number of outstanding shares reverts to its pre-repurchase level after the options are exercised. Third, a company may have excess cash. This may be due to a one-time cash inflow, such as the sale of a division, or the company may simply be generating more free cash flow than it needs to service its debt.[4]

Stock repurchases are usually made in one of three ways. (1) A publicly owned firm can buy back its own stock through a broker on the open market.[5] (2) The firm can make a tender offer, under which it permits stockholders to send in (that is, "tender") shares in exchange for a specified price per share. In this case, the firm generally indicates it will buy up to a specified number of shares within a stated time period (usually about two weeks). If more shares are tendered than the company wants to buy, purchases are made on a pro rata basis. (3) The firm can purchase a block of shares from one large holder on a negotiated basis. This is a targeted stock repurchase, as discussed in Chapter 13.

14-2c Patterns of Cash Distributions

The occurrence of dividends versus stock repurchases has changed dramatically during the past 30 years. First, total cash distributions as a percentage of net income have remained fairly stable at around 26% to 28%, but the mix of dividends and repurchases has changed.[6] The average dividend payout ratio fell from 22.3% in 1974 to 13.8% in 1998, while the average repurchase payout as a percentage of net income rose from 3.7% to 13.6%. Since 1985, large companies have repurchased more shares than they have issued. Since 1998, more cash has been returned to shareholders in repurchases than as dividend payments.

Second, companies today are less likely to pay a dividend. In 1978, about 66.5% of NYSE, AMEX, and NASDAQ firms paid a dividend. In 1999, only 20.8% paid a dividend. Part of this reduction can be explained by the large number of IPOs in the 1990s, because young firms rarely pay a dividend. However, that doesn't explain the entire story, as many mature firms now do not pay dividends. For example, consider the way in which a maturing firm will make its first cash distribution. In 1973, 73% of firms making an initial distribution did so with a dividend. By 1998, only 19% initiated distributions with dividends.[7]

---

[4]See Benton Gup and Doowoo Nam, "Stock Buybacks, Corporate Performance, and EVA," *Journal of Applied Corporate Finance,* Spring 2001, pp. 99–110. The authors show that the firms that repurchase stock have superior operating performance to those that do not buy back stock, which is consistent with the notion that firms buy back stock when they generate additional free cash flow. They also show that operating performance improves in the year after the buyback, indicating that the superior performance is sustainable.

[5]Many firms announce their plans to repurchase stock on the open market. For example, a company might announce it plans to repurchase 4 million shares of stock. However, companies usually don't buy back all the shares they announce but instead repurchase only about 80% of the announced number. See Clifford Stephens and Michael Weisbach, "Actual Share Reacquisitions in Open-Market Repurchase Programs," *Journal of Finance*, February 1998, pp. 313–333.

Third, the aggregate dividend payouts have become more concentrated in the sense that a relatively small number of older, more established, and more profitable firms accounts for most of the cash distributed as dividends.[8]

Fourth, Table 14-1 shows there is considerable variation in distribution policies, with some companies paying a high percentage of their income as dividends. The next section discusses some theories about distribution policies.

SELF-TEST

Explain the procedures used to actually pay the dividend.

Why is the ex-dividend date important to investors?

What are the three ways in which a company can repurchase stock?

14-3 Cash Distributions and Firm Value

A company can change its intrinsic value of operations only if it changes the cost of capital or expected free cash flow. This is true for all corporate decisions, including the distribution policy. Is there an **optimal distribution policy** that maximizes a company's intrinsic value?

The answer depends in part on investors' preferences for returns in the form of dividend yields versus capital gains. The relative mix of dividend yields and capital gains is determined by the **target distribution ratio**, which is the percentage of net income distributed to shareholders through cash dividends or stock repurchases, and the **target payout ratio**, which is the percentage of net income paid as a cash dividend. Notice that the payout ratio must be less than the distribution ratio because the distribution ratio includes stock repurchases as well as cash dividends.

The combination of a high distribution ratio and a high payout ratio means that a company pays large dividends and has small (or zero) stock repurchases. In this situation, the dividend yield is relatively high and the expected capital gain is low. If a company has

[8]For example, see Harry DeAngelo, Linda DeAngelo, and Douglas J. Skinner, "Are Dividends Disappearing? Dividend Concentration and the Consolidation of Earnings," *Journal of Financial Economics*, June 2004, pp. 425–456.

a large distribution ratio but a small payout ratio, then it pays low dividends but regularly repurchases stock, resulting in a low dividend yield but a higher expected capital gain yield. If a company has a low distribution ratio, then it must also have a relatively low payout ratio, again resulting in a low dividend yield and, it is hoped, a relatively high capital gain yield.

In this section, we examine three theories of investor preferences for dividend yield versus capital gains: (1) the dividend irrelevance theory, (2) the dividend preference theory (also called the "bird-in-the-hand" theory), and (3) the tax effect theory.

14-3a Dividend Irrelevance Theory

The original proponents of the **dividend irrelevance theory** were Merton Miller and Franco Modigliani (MM).[9] They argued that the firm's value is determined only by its basic earning power and its business risk. In other words, MM argued that the value of the firm depends only on the income produced by its assets, not on how this income is split between dividends and retained earnings.

To understand MM's argument, recognize that any shareholder can in theory construct his own dividend policy. For example, if a firm does not pay dividends, a shareholder who wants a 5% dividend can "create" it by selling 5% of his stock. Conversely, if a company pays a higher dividend than an investor desires, the investor can use the unwanted dividends to buy additional shares of the company's stock. If investors could buy and sell shares and thus create their own dividend policy without incurring costs, then the firm's dividend policy would truly be irrelevant.

In developing their dividend theory, MM made a number of important assumptions, especially the absence of taxes and brokerage costs. If these assumptions are not true, then investors who want additional dividends must incur brokerage costs to sell shares and must pay taxes on any capital gains. Investors who do not want dividends must incur brokerage costs to purchase shares with their dividends. Because taxes and brokerage costs certainly exist, dividend policy may well be relevant. We will discuss empirical tests of MM's dividend irrelevance theory shortly.

14-3b Dividend Preference (Bird-in-the-Hand) Theory

The principal conclusion of MM's dividend irrelevance theory is that dividend policy does not affect a stock's value or risk. Therefore, it does not affect the required rate of return on equity, r_s. In contrast, Myron Gordon and John Lintner both argued that a stock's risk declines as dividends increase: A return in the form of dividends is a sure thing, but a return in the form of capital gains is risky. In other words, a **bird in the hand** is worth more than two in the bush. Therefore, shareholders prefer dividends and are willing to accept a lower required return on equity.[10]

The possibility of agency costs leads to a similar conclusion. First, high payouts reduce the risk that managers will squander cash because there is less cash on hand. Second, a high-payout company must raise external funds more often than a low-payout company, all else held equal. If a manager knows that the company will receive frequent scrutiny

[9]See Merton H. Miller and Franco Modigliani, "Dividend Policy, Growth, and the Valuation of Shares," *Journal of Business*, October 1961, pp. 411–433. However, their conclusion is valid only if investors expect managers eventually to pay out the equivalent of the present value of all future free cash flows; see Harry DeAngelo and Linda DeAngelo, "The Irrelevance of the MM Dividend Irrelevance Theorem," *Journal of Financial Economics*, Vol. 79, 2006, pp. 293–315.

[10]Myron J. Gordon, "Optimal Investment and Financing Policy," *Journal Of Finance*, May 1963, pp. 264–272; and John Lintner, "Dividends, Earnings, Leverage, Stock Prices, and the Supply of Capital to Corporations," *Review of Economics and Statistics*, August 1962, pp. 243–269.

from external markets, then the manager will be less likely to engage in wasteful practices. Therefore, high payouts reduce the risk of agency costs. With less risk, shareholders are willing to accept a lower required return on equity.

14-3c Tax Effect Theory: Capital Gains Are Preferred

Before 2003, individual investors paid ordinary income taxes on dividends but lower rates on long-term capital gains. The Jobs and Growth Act of 2003 changed this, reducing the tax rate on dividend income to the same as on long-term capital gains.[11] However, there are two reasons why stock price appreciation still is taxed more favorably than dividend income. First, an increase in a stock's price isn't taxable until the investor sells the stock, whereas a dividend payment is taxable immediately; a dollar of taxes paid in the future has a lower effective cost than a dollar paid today because of the time value of money. So even when dividends and gains are taxed equally, capital gains are never taxed sooner than dividends. Second, if a stock is held until the shareholder dies, then no capital gains tax is due at all: The beneficiaries who receive the stock can use its value on the date of death as their cost basis and thus completely escape the capital gains tax.

If dividends are taxed more highly than capital gains, there is a **dividend tax penalty**, causing investors to require a higher pre-tax rate of return on dividend-paying stocks relative to non-dividend stocks. All else equal, investors should be willing to pay more for low-payout companies than for otherwise similar high-payout companies.[12] Therefore, the **tax effect** theory states that investors prefer that companies minimize dividends.

14-3d Empirical Evidence on Distribution Policies

It is very difficult to construct a perfect empirical test of the relationship between payout policy and the required rate of return on stock. First, all factors other than distribution level should be held constant; that is, the sample companies should differ only in their distribution levels. Second, each firm's cost of equity should be measured with a high degree of accuracy. Unfortunately, we cannot find a set of publicly owned firms that differ only in their distribution levels, nor can we obtain precise estimates of the cost of equity. Therefore, no one has yet identified a completely unambiguous relationship between the distribution level and the cost of equity or firm value.

Although none of the empirical tests is perfect, comparing a company's dividend yield with its required rate of return shows that firms with higher dividend payouts also have higher required returns.[13] In other words, investors require a higher pre-tax return to induce them to buy the stock. This tends to support the tax effect hypothesis, although the size of the required return is too high to be fully explained by taxes.

---

[11]Of course, nothing involving taxes is quite this simple. The dividend must be from a domestic company, and the investor must own the stock for more than 60 days during the 120-day period beginning 60 days before the ex-dividend date. There are restrictions for dividends other than regular cash dividends. The Tax Increase Prevention and Reconciliation Act of 2005 cut the long-term capital gains tax rate to zero for low-income investors (that is, those whose marginal tax rate is 15% or less) and kept it at 15% for those with more income. Starting in 2014, the capital gains rates are 0%, 15%, or 20%, depending on income. In addition, higher income filers will pay an additional 3.8% on net investment income, making their effective capital gains rate 23.8%. Also, the Alternative Minimum Tax (AMT) increases the effective tax rate on dividends and capital gains by 7% for some moderately high-income earners. See Leonard Burman, William Gale, Greg Leiserson, and Jeffrey Rohaly, "The AMT: What's Wrong and How to Fix It," *National Tax Journal*, September 2007, pp. 385–405.

Another way to test the hypothesis is to compare companies in countries with different tax codes. Empirical evidence shows that if a country has a relatively small dividend tax penalty, more companies tend to pay dividends and the dividend payments tend to be larger. In contrast, if a country has a relatively high dividend tax penalty, more companies tend to repurchase stock.[14] This evidence is consistent with the tax effect theory.

A different way to test for tax effects is to examine payout policies immediately before tax codes are scheduled to change, such as late 2010 and 2012. Given the previous conflicts within Congress and the conflicts between Congress and President Obama, investors had good reasons to expect that no new tax code would be passed, which meant that previous tax codes with reduced taxes on dividends would expire on December 31. To avoid higher taxes if the tax breaks expired, many companies made unusually large one-time **special dividend** payments late in 2010 and 2012, totaling about $7 billion *more* than were paid in late 2009 and 2011.[15] In addition, around 176 companies moved up their payment dates from the first months of the upcoming year (which would be after the dividend-friendly tax laws expired) to months at the end of the current year, totaling over $12 billion in sooner-than-normal payments. Interestingly, these activities are more pronounced for companies whose insiders own larger proportions of the company's stock. It appears as though insiders are trying to avoid taxes on their own stock holdings as well minimize taxes for the outside shareholders.

The previous evidence suggests that investor prefer to avoid the taxes associated with dividends. However, low dividend payments mean that managers have more discretionary cash and might squander it on perquisites or value-destroying acquisitions. Such agency costs should be most severe in countries with poor investor protection. In such countries, companies with high dividend payouts should be more highly valued than those with low payouts because high payouts limit the extent to which managers can expropriate shareholder wealth. Recent research shows that this is the case, which supports the dividend preference hypothesis in the case of companies with severe agency problems.[16]

The evidence shows that companies definitely take taxation into account when setting dividend policies. However, agency costs can be worse than taxes in some countries, so the evidence is mixed regarding the impact of dividend policy on value.

Although the evidence is not as clear as to whether the *average* investor uniformly prefers either higher or lower distribution levels, other research does show that *individual* investors have strong preferences. Also, other research shows that investors prefer stable, predictable dividend payouts (regardless of the payout level) and that they interpret dividend changes as signals about firms' future prospects. We discuss these issues in the next several sections.

SELF-TEST

What did Modigliani and Miller assume about taxes and brokerage costs when they developed their dividend irrelevance theory?

How did the bird-in-the-hand theory get its name?

What have been the results of empirical tests of the dividend theories?

14-4 Clientele Effect

As we indicated earlier, different groups, or *clienteles,* of stockholders prefer different dividend payout policies. For example, retired individuals, pension funds, and university endowment funds generally prefer cash income, so they may want the firm to pay out a high percentage of its earnings. Such investors are often in low or even zero tax brackets, so taxes are of no concern. On the other hand, stockholders in their peak earning years might prefer reinvestment, because they have less need for current investment income and would simply reinvest dividends received—after first paying income taxes on those dividends.

WWW

For updates of industry payout ratios, go to **www.reuters.com/finance/stocks**. *After picking a company, select Financials tab.*

If a firm retains and reinvests income rather than paying dividends, those stockholders who need current income would be disadvantaged. The value of their stock might increase, but they would be forced to go to the trouble and expense of selling some of their shares to obtain cash. Also, some institutional investors (or trustees for individuals) would be legally precluded from selling stock and then "spending capital." On the other hand, stockholders who are saving rather than spending dividends might favor the low-dividend policy: The less the firm pays out in dividends, the less these stockholders will have to pay in current taxes, and the less trouble and expense they will have to go through to reinvest their after-tax dividends. Therefore, investors who want current investment income should own shares in high–dividend payout firms, while investors with no need for current investment income should own shares in low–dividend payout firms. For example, investors seeking high cash income might invest in the household products industry, which averaged a 100% payout in February 2015, while those favoring growth could invest in the automotive industry, which paid out only 4% during the same time period.

To the extent that stockholders can switch firms, a firm can change from one dividend payout policy to another and then let stockholders who do not like the new policy sell to other investors who do. However, frequent switching would be inefficient because of: (1) brokerage costs, (2) the likelihood that stockholders who are selling will have to pay capital gains taxes, and (3) a possible shortage of investors who like the firm's newly adopted dividend policy. Thus, management should be hesitant to change its dividend policy, because a change might cause current shareholders to sell their stock, forcing the stock price down. Such a price decline might be temporary but might also be permanent—if few new investors are attracted by the new dividend policy, then the stock price would remain depressed. Of course, the new policy might attract an even larger clientele than the firm had before, in which case the stock price would rise.

Evidence from several studies suggests that there is, in fact, a **clientele effect**. For example, low-tax or tax-free institutions hold relatively more high-dividend stocks than taxable investors, and taxable institutions hold fewer high-dividend stocks than non-taxed investors.[17]

There is additional evidence regarding clientele effects at mutual funds based on the tax status of investors.[18] Some mutual fund investors are sheltered from taxes because their investments are made through **401(k) retirement plans**. In 401(k) plans, employees' contributions, matching contributions from the sponsoring employer (if these are included in the plan), and profits on the investments are not taxable until withdrawn. These are called **defined contribution (DC)** plans because the contributions are known

[17]For example, see R. Richardson Pettit, "Taxes, Transactions Costs and the Clientele Effect of Dividends," *Journal of Financial Economics*, December 1977, pp. 419–436; and William J. Moser and Andy Puckett, "Dividend Tax Clienteles: Evidence from Tax Law Changes," *Journal of the American Taxation Association*, Spring 2009, pp. 1–22.

[18]See C. Sialm and L. Starks, "Mutual Fund Tax Clienteles," *Journal of Finance*, August 2012, pp. 1397–1422.

but the future benefits depend on the plans' investments, which often include mutual funds. For tax-liable investors, the dividends paid on stocks held by a mutual fund are taxable income, as are any capital gains recognized when the fund sells stocks for a profit. The evidence shows that mutual funds with a high proportion of taxable investors (i.e., the funds with relatively few DC investors) tend to choose investment strategies that have lower tax burdens than those chosen by funds with a high proportion of DC investors. In other words, the fund managers cater to their investment strategies to be consistent with the tax liabilities of their investors.[19]

MM and others have argued that one clientele is as good as another, so the existence of a clientele effect does not necessarily imply that one dividend policy is better than any other. However, MM may be wrong, and neither they nor anyone else can prove that the aggregate makeup of investors permits firms to disregard clientele effects. This issue, like most others in the dividend arena, is still up in the air.

SELF-TEST

Define the clientele effect, and explain how it affects dividend policy.

14-5 Signaling Hypothesis

When MM set forth their dividend irrelevance theory, they assumed that everyone—investors and managers alike—has identical information regarding a firm's future earnings and dividends. In reality, however, different investors have different views on both the level of future dividend payments and the uncertainty inherent in those payments, and managers have better information about future prospects than public stockholders.

It has been observed that an increase in the dividend is often accompanied by an increase in the price of a stock and that a dividend cut generally leads to a stock price decline. Some have argued this indicates that investors prefer dividends to capital gains. However, MM saw this differently. They noted the well-established fact that corporations are reluctant to cut dividends, which implies that corporations do not raise dividends unless they anticipate higher earnings in the future. Thus, MM argued that a higher-than-expected dividend increase is a signal to investors that the firm's management forecasts good future earnings. Conversely, a dividend reduction, or a smaller-than-expected increase, is a signal that management is forecasting poor earnings in the future. Thus, MM argued that investors' reactions to changes in dividend policy do not necessarily show that investors prefer dividends to retained earnings. Rather, they argue that price changes following dividend actions simply indicate that dividend changes convey information. This is called the dividend **signaling hypothesis**; it is also called the dividend **information content hypothesis**.

The initiation of a dividend by a firm that formerly paid no dividend is certainly a significant change in distribution policy. It appears that initiating firms' future earnings and cash flows are less risky than before the initiation. However, the evidence is mixed regarding the future profitability of initiating firms: Some studies find slightly higher earnings after the initiation but others find no significant change in earnings.[20] What

[19]Interestingly, the mutual funds with a high proportion of DC clients have lower expense ratios, suggesting that sponsoring companies are more concerned about (or more aware of) expenses than are individual investors.

[20]See Edward Dyl and Robert Weigand, "The Information Content of Dividend Initiations: Additional Evidence," *Financial Management*, Autumn 1998, pp. 27–35; P. Asquith and D. Mullins, "The Impact of Initiating Dividend Payments on Shareholders' Wealth," *Journal of Business*, January 1983, pp. 77–96; and P. Healy and K. Palepu, "Earnings Information Conveyed by Dividend Initiations and Omissions," *Journal of Financial Economics*, September 1988, pp. 149–175.

happens when firms with existing dividends unexpectedly increase or decrease the dividend? Early studies, using small data samples, concluded that unexpected dividend changes did not provide a signal about future earnings.[21] However, more recent data with larger samples provide mixed evidence.[22] On average, firms that cut dividends had poor earnings in the years directly preceding the cut but actually improved earnings in subsequent years. Firms that increased dividends had earnings increases in the years preceding the increase but did not appear to have subsequent earnings increases. However, neither did they have subsequent declines in earnings, so it appears that the increase in dividends is a signal that past earnings increases were not temporary. Also, a relatively large number of firms that expect a large permanent increase in cash flow (as opposed to earnings) do in fact increase their dividend payouts in the year prior to the cash flow increase.

All in all, there is clearly some information content in dividend announcements: Stock prices tend to fall when dividends are cut, even if they don't always rise when dividends are increased. However, this doesn't necessarily validate the signaling hypothesis, because it is difficult to tell whether any stock price change following a change in dividend policy reflects only signaling effects or reflects both signaling and dividend preferences.

SELF-TEST

Define signaling content, and explain how it affects dividend policy.

14-6 Implications for Dividend Stability

The clientele effect and the information content in dividend announcements definitely have implications regarding the desirability of stable versus volatile dividends. For example, many stockholders rely on dividends to meet expenses, and they would be seriously inconvenienced if the dividend stream were unstable. Further, reducing dividends to make funds available for capital investment could send incorrect signals to investors, who might push down the stock price because they interpret the dividend cut to mean that the company's future earnings prospects have been diminished. Thus, maximizing its stock price probably requires a firm to maintain a steady dividend policy. Because sales and earnings are expected to grow for most firms, a stable dividend policy means a company's regular cash dividends should also grow at a steady, predictable rate.[23] But, as we explain in the next section, most companies will probably move toward small, sustainable, regular cash dividends that are supplemented by stock repurchases.

Will Dividends Ever Be the Same?

The great recession of 2007 had dramatic effects on dividend policies. According to Standard & Poor's, companies announcing dividend increases exceeded those announcing decreases by a factor of 15 to 1 since 1955—at least until the first 5 months of 2009. Out of 7,000 publicly traded companies, only 283 announced dividend increases in the first quarter of 2009, while 367 cut dividends, a stunning reversal in the normal ratio of increasers to decreasers. Even the S&P 500 companies weren't immune to the crisis, with only 74 increasing dividends as compared with 54 cutting dividends and 9 suspending dividend payments altogether. To put this in perspective, only *one* S&P 500 company cut its dividend during the first quarter of 2007. The dividend decreases in 2009 aren't minor cuts, either. Howard Silverblatt, a Senior Index Analyst at Standard & Poor's, estimates the cuts add up to $77 billion.

How did the market react to cuts by these companies? JPMorgan Chase's stock price went up on the announcement, presumably because investors thought a stronger balance sheet at JPM would increase its intrinsic value by more than the loss investors incurred because of the lower dividend. On the other hand, GE's stock fell by more than 6% on the news of its 68% dividend cut, perhaps because investors feared this was a signal that GE's plight was worse than they had expected.

One thing is for certain: The days of large "permanent" dividends are over!

SELF-TEST

Why do the clientele effect and the information content hypotheses imply that investors prefer stable dividends?

14-7 Setting the Target Distribution Level: The Residual Distribution Model

When deciding how much cash to distribute to stockholders, two points should be kept in mind: (1) The overriding objective is to maximize shareholder value. (2) The firm's cash flows really belong to its shareholders, so a company should not retain income unless managers can reinvest that income to produce returns higher than shareholders could themselves earn by investing the cash in investments of equal risk. On the other hand, recall from Chapter 9 that internal equity (reinvested earnings) is cheaper than external equity (new common stock issues) because it avoids flotation costs and adverse signals. This encourages firms to retain earnings so as to avoid having to issue new stock.

When establishing a distribution policy, one size does not fit all. Some firms produce a lot of cash but have limited investment opportunities—this is true for firms in profitable but mature industries in which few opportunities for growth exist. Such firms typically distribute a large percentage of their cash to shareholders, thereby attracting investment clienteles that prefer high dividends. Other firms generate little or no excess cash because they have many good investment opportunities. Such firms generally don't distribute much cash but do enjoy rising earnings and stock prices, thereby attracting investors who prefer capital gains.

As Table 14-1 suggests, dividend payouts and dividend yields for large corporations vary considerably. Generally, firms in stable, cash-producing industries such as utilities,

financial services, and tobacco, pay relatively high dividends, whereas companies in rapidly growing industries such as computer software tend to pay lower dividends.

For a given firm, the optimal distribution ratio is a function of four factors: (1) investors' preferences for dividends versus capital gains, (2) the firm's investment opportunities, (3) its target capital structure, and (4) the availability and cost of external capital. The last three elements are combined in what we call the **residual distribution model**. Under this model a firm follows these four steps when establishing its target distribution ratio: (1) It determines the optimal capital budget. (2) It determines the amount of equity needed to finance that budget, given its target capital structure (we explain the choice of target capital structures in Chapter 15). (3) It uses reinvested earnings to meet equity requirements to the extent possible. (4) It pays dividends or repurchases stock only if more earnings are available than are needed to support the optimal capital budget. The word *residual* implies "leftover," and the residual policy implies that distributions are paid out of "leftover" earnings.

If a firm rigidly follows the residual distribution policy, then distributions paid in any given year can be expressed as follows:

$$\begin{aligned}\text{Distributions} &= \text{Net income} - \begin{matrix}\text{Retained earnings needed to}\\ \text{finance new investments}\end{matrix}\\ &= \text{Net income} - [(\text{Target equity ratio}) \times (\text{Total capital budget})]\end{aligned} \tag{14-1}$$

As an illustration, consider the case of Texas and Western (T&W) Transport Company, which has $60 million in net income and a target capital structure of 60% equity and 40% debt.

If T&W forecasts poor investment opportunities, then its estimated capital budget will be only $40 million. To maintain the target capital structure, 40% ($16 million) of this capital must be raised as debt and 60% ($24 million) must be equity. If it followed a strict residual policy, T&W would retain $24 million of its $60 million earnings to help finance new investments and then distribute the remaining $36 million to shareholders:

$$\begin{aligned}\text{Distributions} &= \text{Net income} - [(\text{Target equity ratio})(\text{Total capital budget})]\\ &= \$60 - [(60\%)(\$40)]\\ &= \$60 - \$24 = \$36\end{aligned}$$

Under this scenario, the company's distribution ratio would be $36 million ÷ $60 million = 0.6 = 60%. These results are shown in Table 14-2.

In contrast, if the company's investment opportunities are average, its optimal capital budget would rise to $70 million. Here it would require $42 million of retained earnings, so distributions would be $60 − $42 = $18 million, for a ratio of $18/$60 = 30%. Finally, if investment opportunities are good, then the capital budget would be $150 million, which would require 0.6($150) = $90 million of equity. In this case, T&W would retain all of its net income ($60 million) and thus make no distributions. Moreover, because the required equity exceeds the retained earnings, the company would have to issue some new common stock to maintain the target capital structure.

Because investment opportunities and earnings will surely vary from year to year, a strict adherence to the residual distribution policy would result in unstable distributions. One year the firm might make no distributions because it needs the money to finance good investment opportunities, but the next year it might make a large distribution because investment opportunities are poor and so it does not need to retain much.

TABLE 14-2
T&W's Distribution Ratio with $60 Million of Net Income and a 60% Target Equity Ratio When Faced with Different Investment Opportunities (Millions of Dollars)

	Investment Opportunities		
	Poor	**Average**	**Good**
Capital budget	$40	$70	$150
Required equity (0.6 × Capital budget)	$24	$42	$ 90
Net income	$60	$60	$ 60
Required equity (from above)	24	42	90
Distributions paid (NI − Required equity)	$36	$18	−$ 30[a]
Distribution ratio (Dividend/NI)	60%	30%	0%

Note:
[a]With a $150 million capital budget, T&W would retain all of its earnings and also issue $30 million of new stock.

Similarly, fluctuating earnings could also lead to variable distributions, even if investment opportunities were stable. Until now, we have not addressed whether distributions should be in the form of dividends, stock repurchases, or some combination. The next sections discuss specific issues associated with dividend payments and stock repurchases; this is followed by a comparison of their relative advantages and disadvantages.

SELF-TEST

Explain the logic of the residual dividend model and the steps a firm would take to implement it.

Hamilton Corporation has a target equity ratio of 65%, and its capital budget is $2 million. If Hamilton has net income of $1.6 million and follows a residual distribution model, how much will its distribution be? **($300,000)**

14-8 The Residual Distribution Model in Practice

If distributions were solely in the form of dividends, then rigidly following the residual policy would lead to fluctuating, unstable dividends. Because investors dislike volatile regular dividends, r_s (the required return on stock) would be high and the stock price low. Therefore, firms should proceed as follows:

1. Estimate earnings and investment opportunities, on average, for the next 5 or so years.
2. Use this forecasted information and the target capital structure to find the average residual model distributions and dollars of dividends during the planning period.
3. Set a *target payout ratio* based on the average projected data.

Thus, *firms should use the residual policy to help set their long-run target distribution ratios, but not as a guide to the distribution in any one year.*

Companies often use financial forecasting models in conjunction with the residual distribution model discussed here to help understand the determinants of an optimal dividend policy. Most large corporations forecast their financial statements over the next 5 to 10 years. Information on projected capital expenditures and working capital requirements is entered into the model, along with sales forecasts, profit margins, depreciation, and the other elements required to forecast cash flows. The target capital structure is also specified, and the model shows the amount of debt and equity that will be required to

meet the capital budgeting requirements while maintaining the target capital structure. Then, dividend payments are introduced. Naturally, the higher the payout ratio, the greater the required external equity. Most companies use the model to find a dividend pattern over the forecast period (generally 5 years) that will provide sufficient equity to support the capital budget without forcing them to sell new common stock or move the capital structure ratios outside their optimal range.

Some companies set a very low "regular" dividend and then supplement it with an **extra dividend** when times are good, such as Microsoft now does. This **low-regular-dividend-plus-extras policy** ensures that the regular dividend can be maintained "come hell or high water" and that stockholders can count on receiving that dividend under all conditions. Then, when times are good and profits and cash flows are high, the company can either pay a specially designated extra dividend or repurchase shares of stock. Investors recognize that the extras might not be maintained in the future, so they do not interpret them as a signal that the companies' earnings are going up permanently; nor do they take the elimination of the extra as a negative signal.

SELF-TEST

Why is the residual model more often used to establish a long-run payout target than to set the actual year-by-year dividend payout ratio?

How do firms use planning models to help set dividend policy?

14-9 A Tale of Two Cash Distributions: Dividends versus Stock Repurchases

Benson Conglomerate, a prestigious publishing house with several Nobel laureates among its authors, recently began generating positive free cash flow and is analyzing the impact of different distribution policies. Benson anticipates extremely stable cash flows and will use the residual model to determine the level of distributions, but it has not yet chosen the form of the distribution. In particular, Benson is comparing distributions via dividends versus repurchases and wants to know the impact the different methods will have on financial statements, shareholder wealth, the number of outstanding shares, and the stock price.

14-9a The Impact on Financial Statements

Consider first the case in which distributions are in the form of dividends. We begin by forecasting financing statements using the method described in Chapter 12. Figure 14-1 shows inputs in Section 1, the most recent and forecasted financial statements in Sections 2 and 3, and the identification of the preliminary financing surplus or deficit in Section 4.[24] Figure 14-1 shows the most recent financial statements and the forecasted financial statements for the next 2 years. (The file ***Ch14 Tool Kit.xlsx*** shows 4 years of projected statements.) Benson has no debt, so its interest expense is zero. If there is a

[24]The increase in financing is the sum of the increase in spontaneous financing (the sum of accounts payable and accruals), external financing (the increase in long-term debt and common stock), and internal financing (net income less any regular dividends); also, we subtract any beginning of year balance for the line of credit because Benson must pay off the line of credit each year even if it draws on it the next year. The increase in operating assets is the increase in all assets except the short-term investments. We subtract the increase in operating assets from the increase in financing. If the difference is negative, there is a financing deficit that must be met by drawing on the line of credit. If the difference is positive, there is a financing surplus that will be used by paying a special dividend.

Notes:

a. To simplify the example, we assume any short-term investments are held for only part of the year and earn no interest.

b. If there is a financial surplus, it is shown as a short-term investment on December 30. These funds are distributed to investors on December 31, so the balance of short-term investments goes to zero on December 31.

c. Because no special dividends have been paid out as of December 30, the retained earnings balance for that date is equal to the previous year's retained earnings balance plus the current year's net income less the regular dividends. When short-term investments are sold and their proceeds are used to make the special cash dividend payments on December 31, the balance of retained earnings is reduced by the amount of the total dividend payments (which is equal to the regular dividend and the reduction in short-term investments that funded the special dividend).

preliminary financing deficit, Benson will draw on a line of credit. If there is a surplus, Benson will pay a special dividend.

We show balance sheets in Figure 14-1 for both December 30 and 31 of each year to better illustrate the impact of the distribution, which we assume occurs once each year on December 31.[25] We assume that the financing surplus is temporarily used to purchase short-term investments that are held until the distribution to shareholders. At the time of the distribution, all short-term investments will be converted to cash and paid out as special dividends. Thus, the 2017 short-term investments total $671.6 on December 30 and drop to zero on December 31, when they are distributed to investors.[26] Observe that the retained earnings account also drops by $671.6 on December 31 as funds that were previously retained are paid out as dividends.

Now let's consider the case of stock repurchases. The projected income statements and asset portion of the balance sheets are the same whether the distribution is in the form of dividends or repurchases, but this is not true for the liabilities-and-equity side of the balance sheet. Figure 14-2 reports the case in which distributions are in the form of stock repurchases. As in the case of dividend distributions, the December 30 balance of the retained earnings account is equal to the previous retained earnings balance plus the year's net income, because all income is retained. However, when funds in the short-term investments account are used to repurchase stock on December 31, the repurchase is shown as a negative entry in the treasury stock account.

To summarize, the projected income statements and assets are identical whether the distribution is made in the form of dividends or stock repurchases. There also is no difference in liabilities. However, distributions as dividends reduce the retained earnings account, whereas stock repurchases reduce the treasury stock account.

[25]As we noted earlier in the chapter, when dividends are declared, a new current liability called "dividends payable" would be added to current liabilities and then retained earnings would be reduced by that amount. To simplify the example, we ignore that provision and assume that there is no balance sheet effect on the declaration date.

[26]As explained previously, there is a difference between the actual payment date and the ex-dividend date. To simplify the example, we assume that the dividends are paid on the ex-dividend date to the shareholder owning the stock the day before it goes ex-dividend.

159	Total common equity	$8,240.0	$9,323.6	$8,652.0	$9,789.8	$9,084.6
160	Total liabilities & equity	$9,040.0	$10,163.6	$9,492.0	$10,671.8	$9,966.6

Source: See the file ***Ch14 Tool Kit.xlsx***. Numbers are reported as rounded values for clarity, but are calculated using *Excel*'s full precision. Thus, intermediate calculations using the figure's rounded values will be inexact.

Notes:

a. When distributions are made as repurchases, a negative entry equal to the dollar amount of the repurchase is made in the treasury stock account at the time of the repurchase, which occurs when short-term investments are liquidated and used to repurchase stock.

b. No funds are paid out in dividends, so the retained earnings balance is equal to the previous balance plus the year's net income (all net income is being retained).

14-9b The Residual Distribution Model: Application to Full Financial Statements

Figures 14-1 and 14-2 illustrate the residual distribution model in Equation 14-1 as applied to entire financial statements. The projected capital budget is equal to the net addition to total operating capital from the projected balance sheets in Figure 14-1. For example, for 2017 the capital budget is:

$$\begin{aligned}\text{Capital budget} &= (\text{Cash} + \text{Accounts receivable} + \text{Inventories} \\ &\quad + \text{Net plant \& equipment}) \\ &\quad - (\text{Accounts payable} + \text{Accruals}) \\ &= (\$84 - \$80) + (\$1{,}260 - \$1{,}200) + (\$1{,}008 - \$960) \\ &\quad + (\$7{,}140 - \$6{,}800) - (\$672 - \$640) - (\$168 - \$160) \\ &= \$452 - \$40 = \$412\end{aligned}$$

With a 100% target equity ratio and net income of $1,083.6, the residual distribution is:

$$\begin{aligned}\text{Distribution} &= \text{Net income} - [(\text{Target equity ratio})(\text{Total capital budget})] \\ &= \$1{,}083.6 - [(100\%)(\$412)] \\ &= \$1{,}083.6 - \$412 = \$671.6\end{aligned}$$

Notice that this is the same as the financial surplus we calculated in Figure 14-1.

14-9c The Impact of Distributions on Intrinsic Value

What is the impact of cash distributions on intrinsic value? We use Benson Conglomerate to illustrate the answer to that question next.

FREE CASH FLOW

We begin by calculating expected free cash flows and performance measures as shown in Figure 14-3. Notice that Benson's expected return on invested capital is greater than the cost of capital, indicating that the managers are creating value for their shareholders. Also notice that the company is beyond its high-growth phase, so FCF is positive and growing at a constant rate of 5%. Therefore, Benson has cash flow available for distribution to investors.

FIGURE 14-3

Source: See the file ***Ch14 Tool Kit.xlsx***. Numbers are reported as rounded values for clarity, but are calculated using *Excel*'s full precision. Thus, intermediate calculations using the figure's rounded values will be inexact.

Notes:

a. Sum of cash, accounts receivable, and inventories.

b. Sum of accounts payable and accruals.

c. Net operating working capital is equal to operating current assets minus operating current liabilities.

d. Sum of NOWC and net plant & equipment.

e. Net operating profit after taxes = (EBIT)(1 − T). In this example, NOPAT is equal to net income because there is no interest expense or interest income.

f. Change in net operating capital from previous year.

g. FCF = NOPAT − Investment in operating capital.

h. Expected return on invested capital = NOPAT divided by beginning capital.

i. Horizon value at 2020 is immediately after the FCF at 2020 has been paid, which makes the horizon value at 2020 the present value of all FCF from 2021 and beyond when discounted back to 12/31/2020: $HV_{2020} = [FCF_{2020}(1 + g_L)]/(WACC - g_L)$.

j. Value of operation before horizon = $V_{op(t)} = (V_{op(t+1)} + FCF_{t+1}) \Big/ (1 + WACC)$.

THE VALUE OF OPERATIONS

Figure 14-3 also shows the horizon value at 2020, which is the value immediately after the payment of the FCF at 2020—it is the value of all FCF from 2021 and beyond discounted back to 12/31/2020. We can use the projected FCFs to determine the horizon value at the end of the projections and then estimate the value of operations for each year prior to the horizon. For Benson, the horizon value on December 31, 2020, is:

$$\begin{aligned} HV_{12/31/20} &= \frac{FCF_{12/31/20}\ (1+g_L)}{WACC - g_L} \\ &= \frac{\$777.46\ (1+0.05)}{0.12-0.05} = \$11{,}661.9 \end{aligned}$$

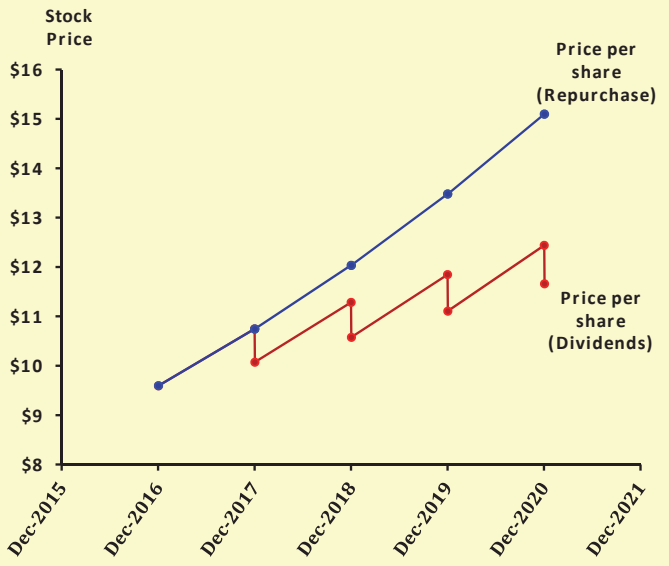
The value of operations on 12/31/2020 is the present value of all FCF from 2021 and beyond discounted back to 12/31/2020, which is exactly the definition of the horizon value on 12/31/2020. Therefore, the value of operations on 12/31/2020 is $11,661.9.

To estimate the value of operations at dates prior to the horizon, consider the following logic. Suppose you own the operations on 12/31/2019 and have just received the 2019 FCF. You plan to sell the operations in a year, after receiving the 2020 FCF. Your expected cash flows in 1 year would be the 2020 FCF and the value at which you expect to sell the operations on 12/31/2020. What is the expected sales price of the operations on 12/31/20? It is the value of all cash flows in 2021 and beyond, discounted back to 12/31/2020, which is the definition of the previously calculated value of 12/31/2020 value of operations. Therefore, the value of operations on 12/31/2019 (immediately after the 2019 FCF has been paid) is the sum of the 12/31/2020 FCF and value of operations, discounted back 1 year at the WACC:

$$\begin{aligned} V_{op(12/31/19)} &= \frac{FCF_{12/31/20} + V_{op(12/31/20)}}{(1+WACC)} \\ &= \frac{\$777.46 + \$11{,}661.9}{1+0.12} = \$11{,}106.6 \end{aligned}$$

We can repeat this process to obtain the current value of operations (i.e., as of December 31, 2016): $9,594.29.

Notice that the choice of how to distribute the residual does not affect the value of operations because the distribution choice does not affect the projected free cash flows.



THE INTRINSIC STOCK PRICE: DISTRIBUTIONS AS DIVIDENDS

Figure 14-4 shows the intrinsic stock price each year using the corporate FCF valuation approach described in Chapters 7 and 12. Section 1 provides calculations assuming cash is distributed via dividends. (See ***Ch14 Tool Kit.xlsx*** for projections for 4 years.) Notice that on December 31 the intrinsic value of equity drops because the firm no longer owns the short-term investments. This causes the intrinsic stock price also to drop. In fact, the drop in stock price is equal to the dividend per share. For example, the 2017 dividend per share (DPS) is $0.67 and the drop in stock price is $10.75 − $10.07 = $0.68 ≈ $0.67. (The penny difference here is due to rounding in intermediate steps.)

Notice that if the stock price did *not* fall by the amount of the DPS, then there would be an opportunity for arbitrage. If the price were to drop by less than the DPS—say, by $0.50 to $10.25—you could buy the stock on December 30 for $10.75, receive a DPS of $0.67 on December 31, and then immediately sell the stock for $10.25, reaping a sure profit of −$10.75 + $0.67 + $10.25 = $0.17. Of course, you'd want to implement this strategy with a million shares, not just a single share. But if everyone tried to use this

Notes:

a. The projected intrinsic stock prices for 4 years are shown in ***Ch14 Tool Kit.xlsx***.

b. The number of shares after the repurchase is $n_{Post} = n_{prior} - (Cash_{Rep}/P_{Prior})$. In this example, the entire amount of ST investments (i.e., the balance of nonoperating assets) is used to repurchase stock.

strategy, the increased demand would drive up the stock price on December 30 until there was no more sure profit to be made. The reverse would happen if investors expected the stock price to fall by more than the DPS.[27]

Here is an important observation: Even though the stock price falls, shareholder wealth does not fall. For example, on December 30, a shareholder owns stock worth $10.75. On December 31, the shareholder owns stock worth $10.07 but has cash of $0.67 from the dividend, for total wealth of $10.75 (subject to rounding differences). Thus, the shareholder's wealth is the same before and after the dividend payment, with the only difference being that part of the shareholder's wealth is in the form of cash from the dividend payment.

THE INTRINSIC STOCK PRICE: DISTRIBUTIONS AS REPURCHASES

Section 2 of Figure 14-4 provides calculations of intrinsic value for the case in which stock is repurchased. Observe that the intrinsic value of equity is the same for both methods of distributions, but the analysis of a repurchase is a little more complicated because the number of shares changes. The key to solving this additional complexity is to recognize that the repurchase does not change the stock price. If the price did change due to the repurchase, then there would be an arbitrage opportunity. For example, suppose the stock price is expected to increase after the repurchase. If this were true, then it should be possible for an investor to buy the stock the day before the repurchase and then reap a reward the very next day. Current stockholders would realize this and would refuse to sell the stock unless they were paid the price that is expected immediately after the repurchase. Now suppose the stock price is expected to fall immediately after the repurchase. In this case, current shareholders should try to sell the stock prior to the repurchase, but their actions would drive the price down to the price that is expected after the repurchase. As you can see, the repurchase itself does not change the stock price.

In summary, the events leading up to a repurchase generate cash (the sale of a division, a recapitalization, or the generation of high free cash flows from operations). Generating cash can certainly change the stock price, but the repurchase itself doesn't change the stock price. We can use this fact to determine the number of shares repurchased. First, though, we must define some notation.

n_{Prior} = The number of shares outstanding prior to the repurchase

n_{Post} = The number of shares outstanding after the repurchase

S_{Prior} = The intrinsic value of equity prior to the repurchase

S_{Post} = The intrinsic value of equity after the repurchase

P_{Prior} = The intrinsic stock price prior to the repurchase

P_{Post} = The intrinsic stock price after the repurchase

$P = P_{Prior} = P_{Post}$ = The intrinsic stock price during, before, and after the repurchase

$Cash_{Rep}$ = The amount of cash used to repurchase shares

[27] We ignore taxes in this description. Empirical evidence suggests that the actual drop in stock price is equal to about 90% of the DPS, with all pre-tax profit being eliminated by taxes.

As we explained, the repurchase itself doesn't change the stock price. Therefore, the number of shares repurchased is equal to the amount of cash used to repurchase stocks divided by the stock price:

$$\text{Number of shares repurchased} = n_{Prior} - n_{Post} = \frac{Cash_{Rep}}{P_{Prior}} \quad \textbf{(14-2)}$$

We can rewrite Equation 14-2 to find an expression for the number of shares after the repurchase:

$$\begin{aligned} n_{Post} &= n_{Prior} - \frac{Cash_{Rep}}{P_{Prior}} \\ &= n_{Prior} - \frac{Cash_{Rep}}{S_{Prior}/n_{Prior}} \\ &= n_{Prior}\left(1 - \frac{Cash_{Rep}}{S_{Prior}}\right) \end{aligned} \quad \textbf{(14-3)}$$

For example, as shown in Section 2 of Figure 14-4, the intrinsic stock price on December 30, 2017, the day before the repurchase, is \$10.75, and there are 1,000 shares of stock. Using Equation 14-3, the number of shares after the repurchase is equal to:

$$\begin{aligned} n_{Post} &= n_{Prior} - \frac{Cash_{Rep}}{P_{Prior}} \\ &= 1{,}000 - \frac{\$671.6}{\$10.75} \\ &= 1{,}000 - 62.47 = 937.5 \end{aligned}$$

Section 2 of Figure 14-4 also shows that on December 31, 2017, the intrinsic value of equity prior to the repurchase, S_{Prior}, drops from \$10,745.6 to a value after the repurchase, S_{Post}, of \$10,074.0. This decrease in the intrinsic value of equity is equal to the amount of the cash used in the repurchase, \$671.6. However, the stock price remains at \$10.75 after the repurchase because the number of shares also drops:

$$P_{Post} = \frac{S_{Post}}{n_{Post}} = \frac{\$10{,}074}{937.5} = \$10.75$$

How does the repurchase affect shareholder wealth? The aggregate value of outstanding stock drops after the repurchase, but the aggregate wealth of the shareholders remains unchanged. Before the repurchase, shareholders own a total of equity worth S_{Prior}, \$10,745.6. After the repurchase, shareholders own a total of equity worth S_{Post}, \$10,074, but they also own cash (received in the repurchase) in the amount of \$671.6, for a total wealth of \$10,745.6. Thus, the repurchase does not change shareholders' aggregate wealth; it only changes the form in which they hold wealth (all stock versus a combination of stock and cash).

COMPARING INTRINSIC STOCK PRICES: DIVIDENDS VERSUS REPURCHASES

The chart at the top of Figure 14-4 shows the projected intrinsic stock prices for the two different distribution methods. Notice that the prices begin at the same level (because Benson has not yet begun making any distributions). The price for the repurchase

scenario climbs smoothly and grows to a higher level than does the price for the dividend scenario, which drops by the DPS each time it is paid. However, the number of shares falls in the repurchase scenario. As shown in Rows 270 and 282 of the figure, the intrinsic values of equity are identical for both distribution methods.

This example illustrates three key results: (1) Ignoring possible tax effects and signals, the total market value of equity will be the same whether a firm pays dividends or repurchases stock. (2) The repurchase itself does not change the stock price (compared with using the cash to buy marketable securities) at the time of the repurchase, although it does reduce the number of outstanding shares. (3) Because a company that repurchases stock will have fewer shares than an otherwise identical company that pays dividends, the stock price of a repurchasing company will climb faster than that of the dividend-paying company. However, the total return to the two companies' shareholders will be the same.[28]

SELF-TEST

Explain how a repurchase changes the number of shares but not the stock price.

A firm's most recent FCF was $2.4 million, and its FCF is expected to grow at a constant rate of 5%. The firm's WACC is 14%, and it has 2 million shares outstanding. The firm has $12 million in short-term investments that it plans to liquidate and then distribute in a stock repurchase; the firm has no other financial investments or debt. Verify that the value of operations is $28 million. Immediately prior to the repurchase, what are the intrinsic value of equity and the intrinsic stock price? **($40 million; $20/share)** *How many shares will be repurchased?* **(0.6 million)** *How many shares will remain after the repurchase?* **(1.4 million)** *Immediately after the repurchase, what are the intrinsic value of equity and the intrinsic stock price?* **($28 million; $20/share)**

14-10 The Pros and Cons of Dividends and Repurchases

The advantages of repurchases can be listed as follows.

1. Repurchase announcements are viewed as positive signals by investors because the repurchase is often motivated by management's belief that the firm's shares are undervalued.[29]
2. Stockholders have a choice when the firm distributes cash by repurchasing stock—they can sell or not sell. Those stockholders who need cash can sell back some of their shares while others can simply retain their stock. With a cash dividend, on the other hand, stockholders must accept a dividend payment.

[28]For more on repurchases, see David J. Denis, "Defensive Changes in Corporate Payout Policy: Share Repurchases and Special Dividends," *Journal of Finance*, December 1990, pp. 1433–1456; Gerald D. Gay, Jayant R. Kale, and Thomas H. Noe, "Share Repurchase Mechanisms: A Comparative Analysis of Efficacy, Shareholder Wealth and Corporate Control Effects," *Financial Management*, Spring 1991, pp. 44–59; Jeffry M. Netter and Mark L. Mitchell, "Stock-Repurchase Announcements and Insider Transactions after the October 1987 Stock Market Crash," *Financial Management*, Autumn 1989, pp. 84–96; William Pugh and John S. Jahera, Jr., "Stock Repurchases and Excess Returns: An Empirical Examination," *The Financial Review*, February 1990, pp. 127–142; and James W. Wansley, William R. Lane, and Salil Sarkar, "Managements' View on Share Repurchase and Tender Offer Premiums," *Financial Management*, Autumn 1989, pp. 97–110.

[29]This is not true for firms that make regular repurchases, but it is true for occasional repurchasers, which are able to buy back stock at a price that is lower than the average price in the surrounding months. See A. Dittmar and L. Field, "Can Managers Time the Market? Evidence Using Repurchase Price Data," *Journal of Financial Economics*, Vol. 115, 2015, pp. 261–282.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

3. Dividends are "sticky" in the short run because management is usually reluctant to raise the dividend if the increase cannot be maintained in the future, and cutting cash dividends is always avoided because of the negative signal it gives. Hence, if the excess cash flow is thought to be only temporary, management may prefer making the distribution in the form of a stock repurchase to declaring an increased cash dividend that cannot be maintained.
4. Companies can use the residual model to set a *target cash distribution* level and then divide the distribution into a *dividend component* and a *repurchase component*. The dividend payout ratio will be relatively low, but the dividend itself will be relatively secure, and it will grow as a result of the declining number of shares outstanding. The company has more flexibility in adjusting the total distribution than it would if the entire distribution were in the form of cash dividends, because repurchases can be varied from year to year without giving adverse signals.
5. Repurchases can be used to produce large-scale changes in capital structures. For example, PepsiCo borrowed $4 billion to use in its stock repurchase plan. The repurchases totaled over 4% of the firm's market value, allowing PepsiCo to quickly change its capital structure.
6. Companies that use stock options as an important component of employee compensation usually repurchase shares in the secondary market and then use those shares when employees exercise their options. This technique allows companies to avoid issuing new shares and thus diluting earnings.

Repurchases have three principal disadvantages.

1. Stockholders may not be indifferent between dividends and capital gains, and the price of the stock might benefit more from cash dividends than from repurchases. Cash dividends are generally dependable, but repurchases are not.
2. The *selling* stockholders may not be fully aware of all the implications of a repurchase, or they may not have all the pertinent information about the corporation's present and future activities. However, in order to avoid potential stockholder suits, firms generally announce repurchase programs before embarking on them.
3. The corporation may pay too much for the repurchased stock—to the disadvantage of remaining stockholders. If the firm seeks to acquire a relatively large amount of its stock, then the price may be bid above its equilibrium level and then fall after the firm ceases its repurchase operations.

When all the pros and cons on stock repurchases versus dividends have been considered, where do we stand? Our conclusions may be summarized as follows.

1. Because of the deferred tax on capital gains, repurchases have a tax advantage over dividends as a way to distribute income to stockholders. This advantage is reinforced by the fact that repurchases provide cash to stockholders who want cash while allowing those who do not need current cash to delay its receipt. On the other hand, dividends are more dependable and thus are better suited for those who need a steady source of income.
2. The danger of signaling effects requires that a company not have volatile dividend payments, which would lower investors' confidence in the company and adversely affect its cost of equity and its stock price. However, cash flows vary over time, as do investment opportunities, so the "proper" dividend in the residual model varies. To get around this problem, a company can set its dividend low enough to keep dividend payments from constraining operations and then use repurchases on a more or less regular basis to distribute excess cash. Such a procedure will provide regular, dependable dividends plus additional cash flow to those stockholders who want it.

Dividend Yields around the World

Dividend yields vary considerably in different stock markets throughout the world. In 1999, dividend yields in the United States averaged 1.6% for the large blue-chip stocks in the Dow Jones Industrials, 1.2% for a broader sample of stocks in the S&P 500, and 0.3% for stocks in the NASDAQ, where high-tech firms predominate. Outside the United States, average dividend yields ranged from 5.7% in New Zealand to 0.7% in Taiwan. The accompanying table summarizes the dividend picture in 1999.

World Stock Market (Index)	Dividend Yield	World Stock Market (Index)	Dividend Yield
New Zealand	5.7%	United States (Dow Jones Industrials)	1.6%
Australia	3.1	Canada (TSE 300)	1.5
Britain (FTSE 100)	2.4	United States (S&P 500)	1.2
Hong Kong	2.4	Mexico	1.1
France	2.1	Japan (Nikkei)	0.7
Germany	2.1	Taiwan	0.7
Belgium	2.0	United States (NASDAQ)	0.3
Singapore	1.7		

Source: From Alexandra Eadie, "On the Grid Looking for Dividend Yield around the World," *The Globe and Mail,* June 23, 1999, p. B16. Eadie's source was Bloomberg Financial Services. Reprinted with permission from *The Globe and Mail.*

3. Repurchases are also useful when a firm wants to make a large shift in its capital structure, wants to distribute cash from a one-time event such as the sale of a division, or wants to obtain shares for use in an employee stock option plan.

SELF-TEST

What are some advantages and disadvantages of stock repurchases?

How can stock repurchases help a company operate in accordance with the residual distribution model?

14-11 Other Factors Influencing Distributions

In this section, we discuss several other factors that affect the dividend decision. These factors may be grouped into two broad categories: (1) constraints on dividend payments and (2) availability and cost of alternative sources of capital.

14-11a Constraints

Constraints on dividend payments can affect distributions, as the following examples illustrate.

1. *Bond indentures*. Debt contracts often limit dividend payments to earnings generated after the loan was granted. Also, debt contracts often stipulate that no dividends can be paid unless the current ratio, times-interest-earned ratio, and other safety ratios exceed stated minimums.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

2. *Preferred stock restrictions*. Typically, common dividends cannot be paid if the company has omitted its preferred dividend. The preferred arrearages must be satisfied before common dividends can be resumed.
3. *Impairment of capital rule*. Dividend payments cannot exceed the balance sheet item "retained earnings." This legal restriction, known as the "impairment of capital rule," is designed to protect creditors. Without the rule, a company in trouble might distribute most of its assets to stockholders and leave its debtholders out in the cold. (*Liquidating dividends* can be paid out of capital, but they must be indicated as such and must not reduce capital below the limits stated in debt contracts.)
4. *Availability of cash*. Cash dividends can be paid only with cash, so a shortage of cash in the bank can restrict dividend payments. However, the ability to borrow can offset this factor.
5. *Penalty tax on improperly accumulated earnings*. To prevent wealthy individuals from using corporations to avoid personal taxes, the Tax Code provides for a special surtax on improperly accumulated income. Thus, if the IRS can demonstrate that a firm's dividend payout ratio is being deliberately held down to help its stockholders avoid personal taxes, the firm is subject to heavy penalties. This factor is generally relevant only to privately owned firms.

14-11b Alternative Sources of Capital

The second factor that influences the dividend decision is the cost and availability of alternative sources of capital.

1. *Cost of selling new stock*. If a firm needs to finance a given level of investment, it can obtain equity by retaining earnings or by issuing new common stock. If flotation costs (including any negative signaling effects of a stock offering) are high, then the required return on new equity, r_e, will be well above the required return on internally generated equity, r_s, making it better to set a low payout ratio and to finance through retention rather than through the sale of new common stock. On the other hand, a high dividend payout ratio is more feasible for a firm whose flotation costs are low. Flotation costs differ among firms—for example, the flotation percentage is generally higher for small firms, so they tend to set low payout ratios.
2. *Ability to substitute debt for equity*. A firm can finance a given level of investment with either debt or equity. As just described, low stock flotation costs permit a more flexible dividend policy because equity can be raised either by retaining earnings or by selling new stock. A similar situation holds for debt policy: If the firm can adjust its debt ratio without raising costs sharply, then it can pay the expected dividend—even if earnings fluctuate—by increasing its debt ratio.
3. *Control*. If management is concerned about maintaining control, it may be reluctant to sell new stock; hence, the company may retain more earnings than it otherwise would. However, if stockholders want higher dividends and a proxy fight looms, then the dividend will be increased.

14-12 Summarizing the Distribution Policy Decision

In practice, the distribution decision is made jointly with capital structure and capital budgeting decisions. The underlying reason for joining these decisions is asymmetric information—managers know more than investors know about their company's prospects. Here is how asymmetric information influences managerial actions.

1. In general, managers do not want to issue new common stock. First, new common stock involves issuance costs—commissions, fees, and so on—and those costs can be avoided by reinvesting earnings to finance equity needs. Second, as we will explain in Chapter 15, asymmetric information causes investors to view new common stock issues as negative signals and thus lowers expectations regarding the firm's future prospects. The end result is that the announcement of a new stock issue usually leads to a decrease in the stock price. Considering the total costs due to issuance and asymmetric information, managers prefer to use retained earnings as the primary source of new equity.
2. Dividend changes provide signals about managers' beliefs concerning their firms' future prospects. Thus, dividend reductions generally have a significant negative effect on a firm's stock price. Because managers recognize this, they try to set dollar dividends low enough so there is only a remote chance the dividend will have to be reduced in the future.

The effects of asymmetric information suggest that, to the extent possible, managers should avoid both new common stock sales and dividend cuts, because both actions tend to lower the stock price. Thus, in setting distribution policy, managers should begin by considering the firm's future investment opportunities relative to its projected internal sources of funds. The target capital structure also plays a part, but because it is a *range*, firms can vary their actual capital structures somewhat from year to year. Because it is best to avoid issuing new common stock, the target long-term payout ratio should be designed to permit the firm to meet all of its equity capital requirements by retaining earnings. In effect, *managers should use the residual model to set dividends, but in a long-term framework*. Finally, the current dollar dividend should be set so that there is an extremely low probability that the dividend, once set, will ever have to be lowered or omitted.

Of course, the dividend decision is made during the planning process, so there is uncertainty about future investment opportunities and operating cash flows. The actual payout ratio in any year will therefore likely be above or below the firm's long-range target. However, the dollar dividend should be maintained, or increased as planned, unless the firm's financial condition deteriorates to the point at which the planned policy simply cannot be maintained. A steady or increasing stream of dividends over the long run signals that the firm's financial condition is under control. Moreover, investor uncertainty is decreased by stable dividends, so a steady dividend stream reduces the negative effect of a new stock issue—should one become absolutely necessary.

In general, firms with superior investment opportunities should set lower payouts, and hence retain more earnings, than firms with poor investment opportunities. The degree of uncertainty also influences the decision. If there is a great deal of uncertainty regarding the forecasts of free cash flows, which are defined here as the firm's operating cash flows minus mandatory equity investments, then it is best to be conservative and to set a lower current dollar dividend. Also, firms with postponable investment opportunities can afford to set a higher dollar dividend, because in times of stress investments can be postponed for a year or two, thus increasing the cash available for dividends. Finally, firms whose cost of capital is largely unaffected by changes in the debt ratio can also afford to set a higher payout ratio, because in times of stress they can more easily issue additional debt to maintain the capital budgeting program without having to cut dividends or issue stock.

The net result of these factors is that many firms' dividend policies are consistent with the life-cycle theory in which younger firms with many investment opportunities but relatively low cash flows reinvest their earnings so that they can avoid the large flotation costs associated with raising external capital.[30] As firms mature and begin to generate more cash flow, they tend to pay more dividends and issue more debt as a way to "bond" their cash flows (as described in Chapter 15) and thereby reduce the agency costs of free cash flow.

What do executives think? A recent survey indicates financial executives believe that it is extremely important to *maintain* dividends but much less important to initiate or increase dividend payments. In general, they view the cash distribution decision as being much less important than capital budgeting decisions. Managers like the flexibility provided by repurchases instead of regular dividends. They tend to repurchase shares when they believe their stock price is undervalued, and they believe that shareholders view repurchases as positive signals. In general, the different taxation of dividends and repurchases is not a major factor when a company chooses how to distribute cash to investors.[31]

14-13 Stock Splits and Stock Dividends

The rationale for stock splits and dividends can best be explained through an example. We will use Porter Electronic Controls Inc., a $700 million electronic components manufacturer, for this purpose. Since its inception, Porter's markets have been expanding, and the company has enjoyed growth in sales and earnings. Some of its earnings have been paid out in dividends, but some are also retained each year, causing its earnings per share and stock price to grow. The company began its life with only a few thousand shares outstanding, and after some years of growth the stock price was high. Porter's CFO thought this high price limited the number of investors who could buy the stock, which reduced demand for the stock and thus kept the firm's total market value below what it could be if there were more shares, at a lower price, outstanding. To correct this situation, Porter "split its stock," as we describe next.

14-13a Stock Splits

Although there is little empirical evidence to support the contention, there is nevertheless a widespread belief in financial circles that an *optimal price range* exists for stocks. "Optimal" means that if the price is within this range, the firm's value will be maximized. Many observers, including Porter's management, believe the best range for most stocks is from $20 to $80 per share. Accordingly, if the price of Porter's stock rose to $80, management would probably declare a 2-for-1 **stock split**, thus doubling the number of shares outstanding, halving the earnings, dividends, and free cash flow per share, and

Talk about a Split Personality!

Sun Microsystems once was among the highest of the high-flying companies in the tech boom of the 1990s. Sun went public in 1986 and its stock price grew rapidly, with Sun declaring seven different 2-1 stock splits between 1988 and 2000. Without these splits, Sun's stock price would have grown from about $30 in late 1988 to over $1,700 in mid-2000, a staggering return of over 40% per year! However, Sun's fortunes fell when the tech bubble burst, and the company never recovered. With its stock price languishing around $5, Sun declared a 1-4 reverse stock split in late 2007, which boosted the stock price to over $20, but subsequently it sank into the $3–$4 range by the spring of 2009. In April 2009, Sun announced that it had agreed to be acquired by Oracle for about $9.50 per share. This would have been only $2.375 = $9.50/4 if not for the reverse split in 2007, quite a fall from its former highs.

Reverse splits were rare when Sun Microsystems declared its split in 2007, but now Sun has plenty of company due to the recession. Such well-known companies as Citigroup and Duke Energy effected reverse splits in 2011 and 2012.

thereby lowering the stock price. Each stockholder would have more shares, but each share would be worth less. If the post-split price were $40, then Porter's stockholders would be exactly as well off as before the split. However, if the stock price were to stabilize above $40, stockholders would be better off. Stock splits can be of any size—for example, the stock could be split 2-for-1, 3-for-1, 1.5-for-1, or in any other way.

Sometimes a company will have a **reverse split**. For example, the financial services company Citigroup (C) was trading in the $55 per share range in 2007 prior to the global financial meltdown. After the meltdown, the stock traded as low as $1 in 2009 and had recovered only to $4.52 per share by May 6, 2011. On May 9, 2011 Citigroup had a 1-10 reverse stock split before trading began, with its shareholders exchanging 10 shares of stock for a single new share. In theory, the stock price should have increased by a factor of 10, to around $45.20, and Citigroup indeed closed that day at a price of $44.16. Even though Citigroup was again trading in the same per share price range as it did before the global financial meltdown, with only 1/10 the number of shares outstanding, its market value of equity was still less than 10% of what it had been in 2007.

14-13b Stock Dividends

Stock dividends are similar to stock splits in that they "divide the pie into smaller slices" without affecting the fundamental position of the current stockholders. For example, with a 5% stock dividend, the holder of 100 shares would receive an additional 5 shares (without cost) and with a 20% stock dividend, the same holder would receive 20 new shares. Again, the total number of shares is increased, so earnings, dividends, free cash flow, and price per share all decline.

If a firm wants to reduce the price of its stock, should it use a stock split or a stock dividend? Stock splits are generally used after a sharp price run-up to produce a large price reduction. Stock dividends used on a regular annual basis will keep the stock price more or less constrained. For example, if a firm's earnings, dividends, and free cash flow were growing at about 10% per year, its stock price would tend to go up at about the same rate, and it would soon be outside the desired trading range. A 10% annual stock dividend would maintain the stock price within the optimal trading range. Note, however, that

small stock dividends create bookkeeping problems and unnecessary expenses, so firms today use stock splits far more often than stock dividends.[32]

14-13c Effect on Stock Prices

If a company splits its stock or declares a stock dividend, will this increase the market value of its stock? Many empirical studies have sought to answer this question. Here is a summary of their findings.

1. On average, the price of a company's stock rises shortly after it announces a stock split or a stock dividend.
2. However, these price increases are probably due to signaling rather than a desire for stock splits or dividends per se. Only managers who think future earnings will be higher tend to split stocks, so investors often view the announcement of a stock split as a positive signal. Thus, it is the signal of favorable prospects for earnings and dividends that causes the price to increase.
3. If a company announces a stock split or stock dividend, its price will tend to rise. However, if during the next few months it does not announce an increase in earnings and dividends, then its stock price will drop back to the earlier level.
4. As we noted earlier, brokerage commissions are generally higher in percentage terms on lower-priced stocks. This means that it is more expensive to trade low-priced than high-priced stocks—which, in turn, means that stock splits may reduce the liquidity of a company's shares. This particular piece of evidence suggests that stock splits/dividends might actually be harmful, although a lower price does mean that more investors can afford to trade in round lots (100 shares), which carry lower commissions than do odd lots (fewer than 100 shares).

What can we conclude from all this? From a purely economic standpoint, stock dividends and splits are just additional pieces of paper. However, they provide management with a relatively low-cost way of signaling that the firm's prospects look good.[33] Further, we should note that since few large, publicly owned stocks sell at prices above several hundred dollars, we simply do not know what the effect would be if Microsoft, Walmart, Hewlett-Packard, and other highly successful firms had never split their stocks and consequently sold at prices in the thousands or even tens of thousands of dollars. All in all, it probably makes sense to employ stock splits (or stock dividends) when a firm's prospects are favorable, especially if the price of its stock has gone beyond the normal trading range.[34]

---

[32]Accountants treat stock splits and stock dividends somewhat differently. For example, in a 2-for-1 stock split, the number of shares outstanding is doubled and the par value is halved. With a stock dividend, a bookkeeping entry is made transferring "retained earnings" to "common stock."

[33]For more on stock splits and stock dividends, see H. Kent Baker, Aaron L. Phillips, and Gary E. Powell, "The Stock Distribution Puzzle: A Synthesis of the Literature on Stock Splits and Stock Dividends," *Financial Practice and Education*, Spring/Summer 1995, pp. 24–37; Maureen Mcnichols and Ajay Dravid, "Stock Dividends, Stock Splits, and Signaling," *Journal of Finance*, July 1990, pp. 857–879; and David R. Peterson and Pamela P. Peterson, "A Further Understanding of Stock Distributions: The Case of Reverse Stock Splits," *Journal of Financial Research*, Fall 1992, pp. 189–205.

[34]It is interesting to note that Berkshire Hathaway (controlled by billionaire Warren Buffett) has never had a stock split, and its stock (BRKa) sold on the NYSE for $223,815 per share in February 2015. Yet in response to investment trusts that were being formed in 1996 to sell fractional units of the stock and thus—in effect—split it, Buffett himself created a new class of Berkshire Hathaway stock (Class B) now worth about 1/1,500 of a Class A (regular) share.

In what situations should managers consider the use of stock dividends?

Suppose you have 1,000 common shares of Burnside Bakeries. The EPS is $6.00, the DPS is $3.00, and the stock sells for $90 per share. Burnside announces a 3-for-1 split. Immediately after the split, how many shares will you have? **(3,000)** *What will the adjusted EPS and DPS be?* **($2 and $1)** *What would you expect the stock price to be?* **($30)**

14-14 Dividend Reinvestment Plans

During the 1970s, most large companies instituted **dividend reinvestment plans (DRIPs)**, under which stockholders can choose to automatically reinvest their dividends in the stock of the paying corporation. Today most large companies offer DRIPs; participation rates vary considerably, but about 25% of the average firm's shareholders are enrolled. There are two types of DRIPs: (1) plans that involve only "old stock" that is already outstanding and (2) plans that involve newly issued stock. In either case, the stockholder must pay taxes on the amount of the dividends, even though stock rather than cash is received.

Under both types of DRIPs, stockholders choose between continuing to receive dividend checks or having the company use the dividends to buy more stock in the corporation. Under the "old stock" type of plan, if a stockholder elects reinvestment, then a bank, acting as trustee, takes the total funds available for reinvestment, purchases the corporation's stock on the open market, and allocates the shares purchased to the participating stockholders' accounts on a pro rata basis. The transaction costs of buying shares (brokerage costs) are low because of volume purchases, so these plans benefit small stockholders who do not need cash dividends for current consumption.

The "new stock" type of DRIP uses the reinvested funds to buy newly issued stock; hence, these plans raise new capital for the firm. AT&T, Union Carbide, and many other companies have used new stock plans to raise substantial amounts of new equity capital. No fees are charged to stockholders, and many companies offer stock at a discount of 3% to 5% below the actual market price. The companies offer discounts as a trade-off against flotation costs that would have been incurred if new stock had been issued through investment bankers instead of through the dividend reinvestment plans.

One interesting aspect of DRIPs is that they cause corporations to re-examine their basic dividend policies. A high participation rate in a DRIP suggests that stockholders might be better off if the firm simply reduced cash dividends, which would save stockholders some personal income taxes. Quite a few firms are surveying their stockholders to learn more about their preferences and to find out how they would react to a change in dividend policy. A more rational approach to basic dividend policy decisions may emerge from this research.

Note that companies start or stop using new stock DRIPs depending on their need for equity capital. For example, Union Carbide and AT&T stopped offering new stock DRIPs with a 5% discount because their needs for equity capital declined.

Some companies have expanded their DRIPs by moving to "open enrollment," whereby anyone can purchase the firm's stock directly and thus bypass brokers' commissions. ExxonMobil not only allows investors to buy their initial shares at no fee but also lets them pick up additional shares through automatic bank account withdrawals. Several

plans, including ExxonMobil's, offer dividend reinvestment for individual retirement accounts, and some, such as U.S. West's, allow participants to invest weekly or monthly rather than on the quarterly dividend schedule. In all of these plans, and many others, stockholders can invest more than the dividends they are forgoing—they simply send a check to the company and buy shares without a brokerage commission. According to First Chicago Trust, which handles the paperwork for 13 million shareholder DRIP accounts, at least half of all DRIPs will offer open enrollment, extra purchases, and other expanded services within the next few years.

SELF-TEST

What are dividend reinvestment plans?

What are their advantages and disadvantages from both the stockholders' and the firm's perspectives?

SUMMARY

- **Distribution policy** involves three issues: (1) What fraction of earnings should be distributed? (2) Should the distribution be in the form of cash dividends or stock repurchases? (3) Should the firm maintain a steady, stable dividend growth rate?
- The **optimal distribution policy** strikes a balance between current dividends and future growth so as to maximize the firm's stock price.
- Miller and Modigliani (MM) developed the **dividend irrelevance theory**, which holds that a firm's dividend policy has no effect on either the value of its stock or its cost of capital.
- The **dividend preference theory**, also called the **bird-in-the-hand theory**, holds that the firm's value will be maximized by a high dividend payout ratio, because investors regard cash dividends as being less risky than potential capital gains.
- The **tax effect theory** states that because long-term capital gains are subject to lower taxes than dividends, investors prefer to have companies retain earnings rather than pay them out as dividends.
- Dividend policy should take account of the **signaling hypothesis**, which is also called the **information content hypothesis**. The signaling effect stems from investors regarding an unexpected dividend change as a signal of management's forecast of future earnings.
- The **clientele effect** suggests that a firm will attract investors who like the firm's dividend payout policy.
- In practice, dividend-paying firms follow a policy of paying a steadily increasing dividend. This policy provides investors with stable, dependable income, and departures from it give investors signals about management's expectations for future earnings.
- Most firms use the **residual distribution model** to set the long-run target distribution ratio at a level that will permit the firm to meet its equity requirements with retained earnings.
- Under a **stock repurchase plan**, a firm buys back some of its outstanding stock, thereby decreasing the number of shares but leaving the stock price unchanged.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- Legal constraints, investment opportunities, availability and cost of funds from other sources, and taxes are also considered when firms establish dividend policies.
- A **stock split** increases the number of shares outstanding. Normally, splits reduce the price per share in proportion to the increase in shares because splits merely "divide the pie into smaller slices." However, firms generally split their stocks only if: (1) The price is quite high. (2) Management thinks the future is bright. Therefore, stock splits are often taken as positive signals and thus boost stock prices.
- A **stock dividend** is a dividend paid in additional shares rather than in cash. Both stock dividends and splits are used to keep stock prices within an "optimal" trading range.
- A **dividend reinvestment plan (DRIP)** allows stockholders to have the company automatically use dividends to purchase additional shares. DRIPs are popular because they allow stockholders to acquire additional shares without brokerage fees.

QUESTIONS

(14-1) Define each of the following terms:

a. Optimal distribution policy
b. Dividend irrelevance theory; bird-in-the-hand theory; tax effect theory
c. Signaling hypothesis; clientele effect
d. Residual distribution model; extra dividend
e. Declaration date; holder-of-record date; ex-dividend date; payment date
f. Dividend reinvestment plan (DRIP)
g. Stock split; stock dividend; stock repurchase

(14-2) How would each of the following changes tend to affect aggregate payout ratios (that is, the average for all corporations), other things held constant? Explain your answers.

a. An increase in the personal income tax rate
b. A liberalization of depreciation for federal income tax purposes—that is, faster tax write-offs
c. A rise in interest rates
d. An increase in corporate profits
e. A decline in investment opportunities
f. Permission for corporations to deduct dividends for tax purposes as they now do interest charges
g. A change in the Tax Code so that both realized and unrealized capital gains in any year were taxed at the same rate as dividends

(14-3) What is the difference between a stock dividend and a stock split? As a stockholder, would you prefer to see your company declare a 100% stock dividend or a 2-for-1 split? Assume that either action is feasible.

(14-4) One position expressed in the financial literature is that firms set their dividends as a residual after using income to support new investments. Explain what a residual policy implies (assuming that all distributions are in the form of dividends), illustrating your answer with a table showing how different investment opportunities could lead to different dividend payout ratios.

(14-5) Indicate whether the following statements are true or false. If the statement is false, explain why.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

a. If a firm repurchases its stock in the open market, the shareholders who tender the stock are subject to capital gains taxes.
b. If you own 100 shares in a company's stock and the company's stock splits 2-for-1, then you will own 200 shares in the company following the split.
c. Some dividend reinvestment plans increase the amount of equity capital available to the firm.
d. The Tax Code encourages companies to pay a large percentage of their net income in the form of dividends.
e. A company that has established a clientele of investors who prefer large dividends is unlikely to adopt a residual dividend policy.
f. If a firm follows a residual dividend policy then, holding all else constant, its dividend payout will tend to rise whenever the firm's investment opportunities improve.

SELF-TEST PROBLEMS

Solutions Shown in Appendix A

(ST-1) Residual Dividend

Components Manufacturing Corporation (CMC) has 1 million shares of stock outstanding. CMC has a target capital structure with 60% equity and 40% debt. The company projects net income of $5 million and investment projects requiring $6 million in the upcoming year.

a. CMC uses the residual distribution model and pays all distributions in the form of dividends. What is the projected DPS?
b. What is the projected payout ratio?

(ST-2) Repurchase or Dividend

Burns & Kennedy Corporation (BK) has a value of operations equal to $2,100, short-term investments of $100, debt of $200, and 100 shares of stock.

a. What is BK's estimated intrinsic stock price?
b. If BK converts its short-term investments to cash and pays a total of $100 in dividends, what is the resulting estimated intrinsic stock price?
c. If BK converts its short-term investments to cash and repurchases $100 of its stock, what is the resulting estimated intrinsic stock price and how many shares remain outstanding?

PROBLEMS

Answers Are in Appendix B

EASY PROBLEMS 1–5

(14-1) Residual Distribution Model

Puckett Products is planning for $5 million in capital expenditures next year. Puckett's target capital structure consists of 60% debt and 40% equity. If net income next year is $3 million and Puckett follows a residual distribution policy with all distributions as dividends, what will be its dividend payout ratio?

(14-2) Residual Distribution Policy

Petersen Company has a capital budget of $1.2 million. The company wants to maintain a target capital structure that is 60% debt and 40% equity. The company forecasts that its net income this year will be $600,000. If the company follows a residual distribution model and pays all distributions as dividends, what will be its payout ratio?

(14-3) Dividend Payout

The Wei Corporation expects next year's net income to be $15 million. The firm's debt ratio is currently 40%. Wei has $12 million of profitable investment opportunities, and it wishes to maintain its existing debt ratio. According to the residual distribution model (assuming all payments are in the form of dividends), how large should Wei's dividend payout ratio be next year?

(14-4) Stock Repurchase

A firm has 10 million shares outstanding with a market price of $20 per share. The firm has $25 million in extra cash (short-term investments) that it plans to use in a stock repurchase; the firm has no other financial investments or any debt. What is the firm's value of operations, and how many shares will remain after the repurchase?

(14-5) Stock Split

JPix management is considering a stock split. JPix currently sells for $120 per share and a 3-for-2 stock split is contemplated. What will be the company's stock price following the stock split, assuming that the split has no effect on the total market value of JPix's equity?

INTERMEDIATE PROBLEMS 6–9

(14-6) External Equity Financing

Gardial GreenLights, a manufacturer of energy-efficient lighting solutions, has had such success with its new products that it is planning to substantially expand its manufacturing capacity with a $15 million investment in new machinery. Gardial plans to maintain its current 30% debt-to-total-assets ratio for its capital structure and to maintain its dividend policy in which at the end of each year it distributes 55% of the year's net income. This year's net income was $8 million. How much external equity must Gardial seek now to expand as planned?

(14-7) Stock Split

Suppose you own 2,000 common shares of Laurence Incorporated. The EPS is $10.00, the DPS is $3.00, and the stock sells for $80 per share. Laurence announces a 2-for-1 split. Immediately after the split, how many shares will you have, what will the adjusted EPS and DPS be, and what would you expect the stock price to be?

(14-8) Stock Split

Fauver Enterprises declared a 3-for-1 stock split last year, and this year its dividend is $1.50 per share. This total dividend payout represents a 6% increase over last year's pre-split total dividend payout. What was last year's dividend per share?

(14-9) Residual Distribution Policy

Harris Company must set its investment and dividend policies for the coming year. It has three independent projects from which to choose, each of which requires a $3 million investment. These projects have different levels of risk, and therefore different costs of capital. Their projected IRRs and costs of capital are as follows:

Project A:	Cost of capital = 17%; IRR = 20%
Project B:	Cost of capital = 13%; IRR = 10%
Project C:	Cost of capital = 7%; IRR = 9%

Harris intends to maintain its 35% debt and 65% common equity capital structure, and its net income is expected to be $4,750,000. If Harris maintains its residual dividend policy (with all distributions in the form of dividends), what will its payout ratio be?

CHALLENGING PROBLEMS 10–12

(14-10) Alternative Dividend Policies

Boehm Corporation has had stable earnings growth of 8% a year for the past 10 years and in 2016 Boehm paid dividends of $2.6 million on net income of $9.8 million. However, in 2017 earnings are expected to jump to $12.6 million, and Boehm plans to invest $7.3 million in a plant expansion. This one-time unusual earnings growth won't be maintained, though, and after 2017 Boehm will return to its previous 8% earnings growth rate. Its target debt ratio is 35%.

a. Calculate Boehm's total dividends for 2017 under each of the following policies:
   (1) Its 2017 dividend payment is set to force dividends to grow at the long-run growth rate in earnings.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(2) It continues the 2016 dividend payout ratio.
(3) It uses a pure residual policy with all distributions in the form of dividends (35% of the $7.3 million investment is financed with debt).
(4) It employs a regular-dividend-plus-extras policy, with the regular dividend being based on the long-run growth rate and the extra dividend being set according to the residual policy.

b. Which of the preceding policies would you recommend? Restrict your choices to the ones listed, but justify your answer.
c. Does a 2017 dividend of $9 million seem reasonable in view of your answers to Parts a and b? If not, should the dividend be higher or lower?

(14-11) Residual Distribution Model

Kendra Brown is analyzing the capital requirements for Reynold Corporation for next year. Kendra forecasts that Reynold will need $15 million to fund all of its positive-NPV projects and her job is to determine how to raise the money. Reynold's net income is $11 million, and it has paid a $2 dividend per share (DPS) for the past several years (1 million shares of common stock are outstanding); its shareholders expect the dividend to remain constant for the next several years. The company's target capital structure is 30% debt and 70% equity.

a. Suppose Reynold follows the residual model and makes all distributions as dividends. How much retained earnings will it need to fund its capital budget?
b. If Reynold follows the residual model with all distributions in the form of dividends, what will be its dividend per share and payout ratio for the upcoming year?
c. If Reynold maintains its current $2 DPS for next year, how much retained earnings will be available for the firm's capital budget?
d. Can Reynold maintain its current capital structure, maintain its current dividend per share, and maintain a $15 million capital budget *without* having to raise new common stock? Why or why not?
e. Suppose management is firmly opposed to cutting the dividend; that is, it wishes to maintain the $2 dividend for the next year. Suppose also that the company is committed to funding all profitable projects and is willing to issue more debt (along with the available retained earnings) to help finance the company's capital budget. Assume the resulting change in capital structure has a minimal impact on the company's composite cost of capital, so that the capital budget remains at $15 million. What portion of this year's capital budget would have to be financed with debt?
f. Suppose once again that management wants to maintain the $2 DPS. In addition, the company wants to maintain its target capital structure (30% debt, 70% equity) and its $15 million capital budget. What is the minimum dollar amount of new common stock the company would have to issue in order to meet all of its objectives?
g. Now consider the case in which management wants to maintain the $2 DPS and its target capital structure but also wants to avoid issuing new common stock. The company is willing to cut its capital budget in order to meet its other objectives. Assuming the company's projects are divisible, what will be the company's capital budget for the next year?
h. If a firm follows the residual distribution policy, what actions can it take when its forecasted retained earnings are less than the retained earnings required to fund its capital budget?

(14-12) Stock Repurchase

Bayani Bakery's most recent FCF was $48 million; the FCF is expected to grow at a constant rate of 6%. The firm's WACC is 12%, and it has 15 million shares of common stock outstanding. The firm has $30 million in short-term investments, which it plans to

liquidate and distribute to common shareholders via a stock repurchase; the firm has no other nonoperating assets. It has $368 million in debt and $60 million in preferred stock.

a. What is the value of operations?
b. Immediately prior to the repurchase, what is the intrinsic value of equity?
c. Immediately prior to the repurchase, what is the intrinsic stock price?
d. How many shares will be repurchased? How many shares will remain after the repurchase?
e. Immediately after the repurchase, what is the intrinsic value of equity? The intrinsic stock price?

SPREADSHEET PROBLEM

(14-13) Build a Model: Distributions as Dividends or Repurchases

resource

Start with the partial model in the file ***Ch14 P13 Build a Model.xlsx*** on the textbook's Web site. J. Clark Inc. (JCI), a manufacturer and distributor of sports equipment, has grown until it has become a stable, mature company. Now JCI is planning its first distribution to shareholders. (See the file for the most recent year's financial statements and projections for the next year, 2017; JCI's fiscal year ends on June 30.) JCI plans to liquidate and distribute $500 million of its short-term securities on July 1, 2017, the first day of the next fiscal year, but it has not yet decided whether to distribute with dividends or with stock repurchases.

a. Assume first that JCI distributes the $500 million as dividends. Fill in the missing values in the file's balance sheet column for July 1, 2017, which is labeled "Distribute as Dividends." (*Hint:* Be sure that the balance sheets balance after you fill in the missing items.) Assume that JCI did not have to establish an account for dividends payable prior to the distribution.
b. Now assume that JCI distributes the $500 million through stock repurchases. Fill in the missing values in the file's balance sheet column for July 1, 2017, which is labeled "Distribute as Repurchase." (*Hint:* Be sure that the balance sheets balance after you fill in the missing items.)
c. Calculate JCI's projected free cash flow; the tax rate is 40%.
d. What is JCI's current intrinsic stock price (the price on 6/30/2016)? What is the projected intrinsic stock price for 6/30/2017?
e. What is the projected intrinsic stock price on 7/1/2017 if JCI distributes the cash as dividends?
f. What is the projected intrinsic stock price on 7/1/2017 if JCI distributes the cash through stock repurchases? How many shares will remain outstanding after the repurchase?

MINI CASE

Integrated Waveguide Technologies (IWT) is a 6-year-old company founded by Hunt Jackson and David Smithfield to exploit metamaterial plasmonic technology to develop and manufacture miniature microwave frequency directional transmitters and receivers for use in mobile Internet and communications applications. IWT's technology, although highly advanced, is relatively inexpensive to implement, and its patented manufacturing techniques require little capital as compared to many electronics fabrication ventures. Because of the low capital requirement, Jackson and Smithfield have been able to avoid issuing new stock and thus own all of the shares. Because of the explosion in demand for its mobile Internet applications, IWT must now access outside equity capital to fund its

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

growth, and Jackson and Smithfield have decided to take the company public. Until now, Jackson and Smithfield have paid themselves reasonable salaries but routinely reinvested all after-tax earnings in the firm, so dividend policy has not been an issue. However, before talking with potential outside investors, they must decide on a dividend policy.

Your new boss at the consulting firm Flick and Associates, which has been retained to help IWT prepare for its public offering, has asked you to make a presentation to Jackson and Smithfield in which you review the theory of dividend policy and discuss the following issues.

a. (1) What is meant by the term "distribution policy"? How has the mix of dividend payouts and stock repurchases changed over time?
   (2) The terms "irrelevance," "dividend preference" (or "bird-in-the-hand"), and "tax effect" have been used to describe three major theories regarding the way dividend payouts affect a firm's value. Explain these terms, and briefly describe each theory.
   (3) What do the three theories indicate regarding the actions management should take with respect to dividend payouts?
   (4) What results have empirical studies of the dividend theories produced? How does all this affect what we can tell managers about dividend payouts?

b. Discuss the effects on distribution policy consistent with: (1) the signaling hypothesis (also called the information content hypothesis) and (2) the clientele effect.

c. (1) Assume that IWT has completed its IPO and has a $112.5 million capital budget planned for the coming year. You have determined that its present capital structure (80% equity and 20% debt) is optimal, and its net income is forecasted at $140 million. Use the residual distribution approach to determine IWT's total dollar distribution. Assume for now that the distribution is in the form of a dividend. Suppose IWT has 100 million shares of stock outstanding. What is the forecasted dividend payout ratio? What is the forecasted dividend per share? What would happen to the payout ratio and DPS if net income were forecasted to decrease to $90 million? To increase to $160 million?
   (2) In general terms, how would a change in investment opportunities affect the payout ratio under the residual distribution policy?
   (3) What are the advantages and disadvantages of the residual policy? (*Hint:* Don't neglect signaling and clientele effects.)

d. (1) Describe the procedures a company follows when it makes a distribution through dividend payments.
   (2) What is a stock repurchase? Describe the procedures a company follows when it makes a distribution through a stock repurchase.

e. Discuss the advantages and disadvantages of a firm repurchasing its own shares.

f. Suppose IWT has decided to distribute $50 million, which it presently is holding in liquid short-term investments. IWT's value of operations is estimated to be about $1,937.5 million, and it has $387.5 million in debt (it has no preferred stock). As mentioned previously, IWT has 100 million shares of stock outstanding.
   (1) Assume that IWT has not yet made the distribution. What is IWT's intrinsic value of equity? What is its intrinsic stock price per share?
   (2) Now suppose that IWT has just made the $50 million distribution in the form of dividends. What is IWT's intrinsic value of equity? What is its intrinsic stock price per share?
   (3) Suppose instead that IWT has just made the $50 million distribution in the form of a stock repurchase. Now what is IWT's intrinsic value of equity? How many shares did IWT repurchase? How many shares remained outstanding after the repurchase? What is its intrinsic stock price per share after the repurchase?

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

g. Describe the series of steps that most firms take when setting dividend policy.
h. What are stock splits and stock dividends? What are the advantages and disadvantages of each?
i. What is a dividend reinvestment plan (DRIP), and how does it work?

SELECTED ADDITIONAL CASES

The following cases from CengageCompose cover many of the concepts discussed in this chapter and are available at **http://compose.cengage.com.**

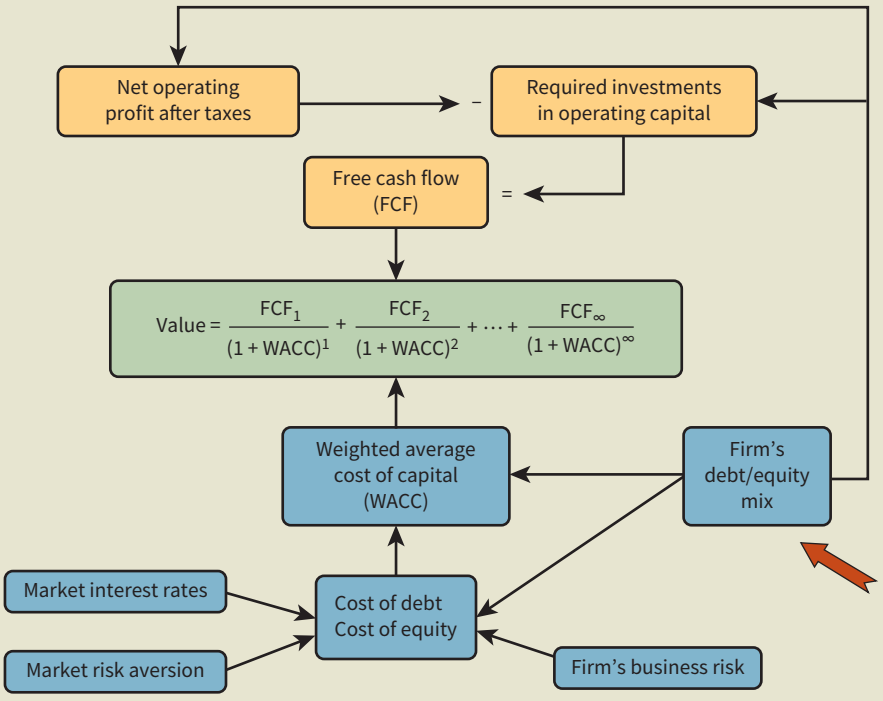
CHAPTER 15

Capital Structure Decisions

A bankruptcy and a liquidity crisis are very different. An *economic* bankruptcy means that the intrinsic value of a company's assets (which is determined by the cash flows those assets are expected to produce) is less than the amount owed to creditors. A *legal* bankruptcy occurs when a company files in bankruptcy court for protection from its creditors until it can arrange an orderly reorganization or liquidation. A *liquidity crisis* occurs when a company doesn't have access to enough cash to make payments to creditors as the payments come due in the near future. In normal times, a strong company (one whose market value of assets far exceeds the amount owed to creditors) can usually borrow money in the short-term credit markets to meet any urgent liquidity needs. Thus, a liquidity crisis usually doesn't trigger a bankruptcy.

However, 2008 and 2009 were anything but usual. Many companies had loaded up on debt during the boom years prior to 2007, and much of that was short-term debt. When the mortgage crisis began in late 2007 and spread like wildfire through the financial sector, many financial institutions virtually stopped providing short-term credit as they tried to stave off their own bankruptcies. As a result, many nonfinancial companies faced liquidity crises. Even worse, consumer demand began to drop and investors' risk aversion began to rise, leading to falling market values of assets and triggering economic and legal bankruptcy for many companies.

The economic crisis drove many companies into bankruptcy, including Lehman Brothers, Washington Mutual, General Motors, Chrysler, Pilgrim's Pride, and Circuit City. Many other companies scrambled to reduce their liquidity problems. For example, Black & Decker (B&D) issued about $350 million in 5-year notes and used the proceeds to pay off some of its commercial paper. Even though the interest rate on Black & Decker's 5-year notes was higher than the rates on its commercial paper, B&D did not have to repay the note for five years, whereas it had to refinance the commercial paper each time it came due.



As you read the chapter, think of these companies that suffered or failed because they mismanaged their capital structure decisions.

Corporate Valuation and Capital Structure

A firm's financing choices obviously have a direct effect on the weighted average cost of capital (WACC). Financing choices also have an indirect effect on the costs of debt and equity because they change the risk and required returns of debt and equity. Financing choices can also affect free cash flows if the probability of bankruptcy becomes high. This chapter focuses on the debt–equity choice and its effect on value.

resource

The textbook's Web site contains an Excel *file that will guide you through the chapter's calculations. The file for this chapter is* ***Ch15 Tool Kit.xlsx****, and we encourage you to open the file and follow along as you read the chapter.*

As explained in Chapter 12, growth in sales requires growth in operating capital, and this often requires that external funds be raised through a combination of equity and debt. The firm's mixture of debt and equity is called its **capital structure**. Although actual levels of debt and equity may vary somewhat over time, most firms try to keep their financing mix close to a **target capital structure**. A firm's **capital structure decision** includes its choice of a target capital structure, the average maturity of its debt, and the specific types of financing it decides to use at any particular time. As with operating decisions, managers should make capital structure decisions that are designed to maximize the firm's intrinsic value.

15-1 An Overview of Capital Structure

The value of a firm's operations is the present value of its expected future free cash flows (FCF) discounted at its weighted average cost of capital (WACC):

$$V_{op} = \sum_{t=1}^{\infty} \frac{FCF_t}{(1 + WACC)^t} \qquad (15\text{-}1)$$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The WACC of a firm financed only by debt and common stock depends on the percentages of debt and common stock (w_d and w_s), the cost of debt (r_d), the cost of stock (r_s), and the corporate tax rate (T):

$$WACC = w_d(1 - T)r_d + w_s r_s \quad \textbf{(15-2)}$$

As these equations show, the only way any decision can change the value of operations is by changing either expected free cash flows or the cost of capital. As you read the chapter, think about the ways the capital structure choices can affect FCF or the WACC.

Table 15-1 shows that the average long-term debt-to-equity ratio diverges widely for different business sectors, ranging from 7% in Health Care to 80% in Utilities. However, sub-sector industries within a sector also have a wide dispersion of ratios. For example, the Consumer Discretionary sector's average is 38%, but two of its sub-sectors are *Advertising* and *Apparel, Accessories & Luxury (AA&L) Goods,* which have average ratios of 12% and 46%, respectively. Companies within a sub-sector also have considerable variation: Coach and Tiffany are in the *AA&L Goods* sub-sector, but Coach has no debt and Tiffany has a 31% ratio. Why do we see such variation across companies and business sectors? Can a company make itself more valuable through its choice of debt ratio? We address these questions in the rest of this chapter, beginning with a description of business risk and financial risk.

TABLE 15-1
Long-Term Debt-to-Equity Ratios for Business Sectors, Selected Sub-Sectors, and Selected Firms

	Long-Term Debt-to-Equity Ratio		
Name of Sector	**Company**	**Sub-Sector**	**Sector**
Consumer Discretionary			38%
Selected Sub-Sectors in Consumer Discretionary:			
Advertising		*12%*	
Apparel, Accessories & Luxury (AA&L) Goods		*46%*	
Selected Companies in AA&L Goods			
Coach	0%		
Tiffany	31%		
Consumer Staples			10%
Energy			38%
Financials			26%
Health Care			7%
Industrials			50%
Information Technology			14%
Materials			50%
Telecommunications Services			79%
Utilities			80%

SELF-TEST

What are some ways in which the capital structure decisions can affect the value of operations?

15-2 Business Risk and Financial Risk

Business risk and financial risk combine to determine the total risk of a firm's future return on equity, as we explain in the next sections.

15-2a Business Risk and Operating Leverage

Business risk is the risk a firm's common stockholders would face if the firm had no debt. In other words, it is the risk inherent in the firm's operations, which arises from uncertainty about future operating profits and capital requirements.

Business risk depends on a number of factors, beginning with variability in product demand and production costs. If a high percentage of a firm's costs are fixed and hence do not decline when demand falls, then the firm has high *operating leverage,* which increases its business risk.

A high degree of **operating leverage** implies that a relatively small change in sales results in a relatively large change in earnings before interest and taxes (EBIT), net operating profits after taxes (NOPAT), return on invested capital (ROIC), return on assets (ROA), and return on equity (ROE). Other things held constant, the higher a firm's fixed costs, the greater its operating leverage. Higher fixed costs are generally associated with: (1) highly automated, capital-intensive firms; (2) businesses that employ highly skilled workers who must be retained and paid even when sales are low; and (3) firms with high product development costs that must be maintained to complete ongoing R&D projects.

To illustrate the relative impact of fixed versus variable costs, consider Strasburg Electronics Company, a manufacturer of components used in cell phones. Strasburg is considering several different operating technologies and several different financing alternatives. We will analyze its financing choices in the next section, but for now we will focus on its operating plans.

Strasburg is comparing two plans, each requiring a capital investment of $200 million; assume for now that Strasburg will finance its choice entirely with equity. Each plan is expected to produce 110 million units (Q) per year at a sales price (P) of $2 per unit. As shown in Figure 15-1, Plan A's technology requires a smaller annual fixed cost (F) than Plan U's, but Plan A has higher variable costs (V). (We denote the second plan with U because it has no financial leverage, and we denote the third plan with L because it does have financial leverage; Plan L is discussed in the next section.) Figure 15-1 also shows the projected income statements and selected performance measures for the first year. Notice that Plan U's performance measures are superior to Plan A's if the expected sales occur.

Notice that the projections in Figure 15-1 are based on the 110 million units expected to be sold. But what if demand is lower than expected? It often is useful to know how far sales can fall before operating profits become negative. The **operating break-even point** occurs when earnings before interest and taxes (EBIT) equal zero:[1]

$$\text{EBIT} = \text{PQ} - \text{VQ} - \text{F} = 0 \qquad (15\text{-}3)$$

[1]This definition of the break-even point does not include any fixed financial costs because it focuses on operating profits. We could also examine net income, in which case a firm with debt would have negative net income even at the operating break-even point. We introduce financial costs shortly.

FIGURE 15-1
Illustration of Operating and Financial Leverage (Millions of Dollars and Millions of Units, Except Per Unit Data)

	A	B	C	D	E
14	*1. Input Data*		Plan A	Plan U	Plan L
15	Required operating current assets		$3	$3	$3
16	Required long-term assets		$199	$199	$199
17	Total assets		$202	$202	$202
18	Resulting operating current liabilities		$2	$2	$2
19	Required capital (TA Op. CL)		$200	$200	$200
20	Book equity		$200	$200	$150
21	Debt		$0	$0	$50
22	Interest rate		8%	8%	8%
23	Sales price (P)		$2.00	$2.00	$2.00
24	Tax rate (T)		40%	40%	40%
25	Expected units sold (Q)		110	110	110
26	Fixed costs (F)		$20	$60	$60
27	Variable costs (V)		$1.50	$1.00	$1.00
28	*2. Income Statements*		Plan A	Plan U	Plan L
29	Sales revenue (P x Q)		$220.0	$220.0	$220.0
30	Fixed costs		20.0	60.0	60.0
31	Variable costs (V x Q)		165.0	110.0	110.0
32	EBIT		$35.0	$50.0	$50.0
33	Interest		0.0	0.0	4.0
34	Pre-tax earnings		$35.0	$50.0	$46.0
35	Tax		14.0	20.0	18.4
36	Net income		$21.0	$30.0	$27.6
37	*3. Key Performance Measures*		Plan A	Plan U	Plan L
38	NOPAT = EBIT(1 T)		$21.0	$30.0	$30.0
39	ROIC = NOPAT/Capital		10.5%	15.0%	15.0%
40	ROA = NI/Total assets		10.4%	14.9%	13.7%
41	ROE = NI/Equity		10.5%	15.0%	18.4%

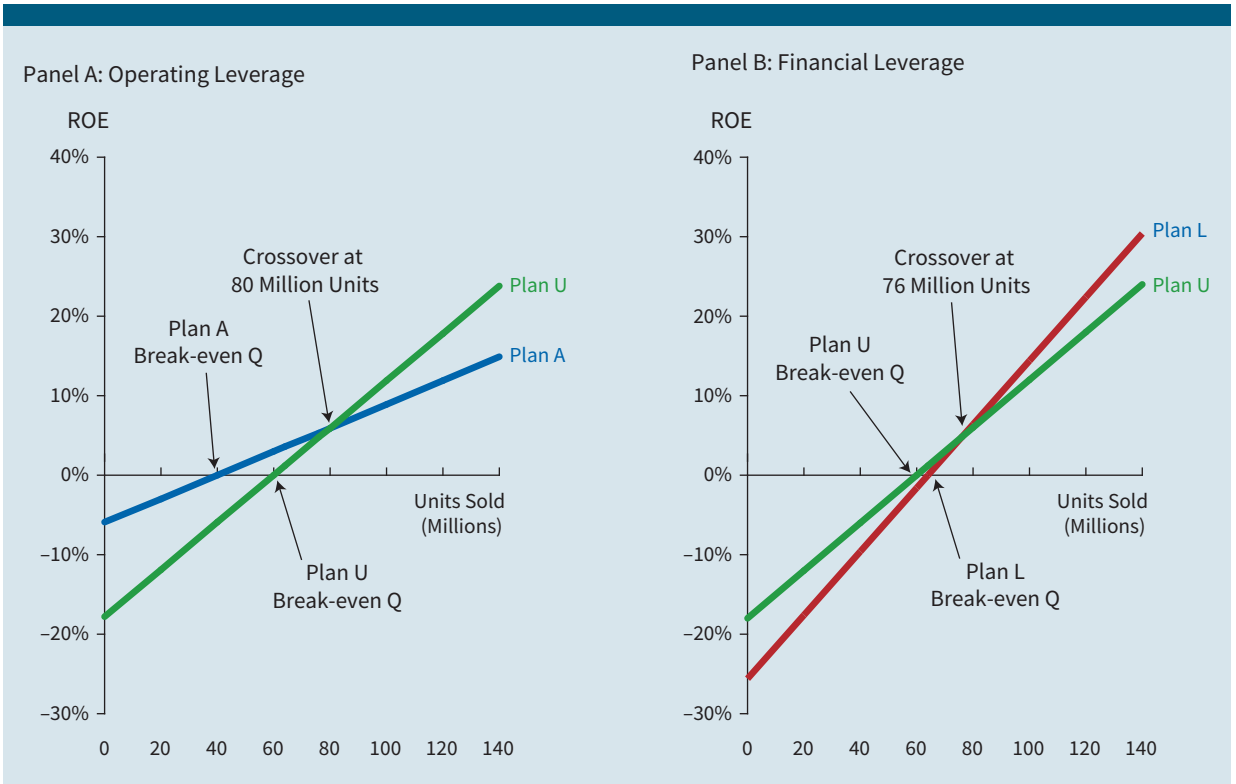
Source: See the file ***Ch15 Tool Kit.xlsx***. Numbers are reported as rounded values for clarity, but are calculated using *Excel*'s full precision. Thus, intermediate calculations using the figure's rounded values will be inexact.

Note: ROA is not exactly equal to ROE for Plan L or Plan U, because total assets are not quite equal to equity for these plans. This is because the operating current liabilities, such as accounts payable and accruals, reduce the required equity capital investment.

If we solve for the break-even quantity, Q_{BE}, we get this expression:

$$Q_{BE} = \frac{F}{P - V} \tag{15-4}$$

The break-even quantities for Plans A and U are:



$$\text{Plan A: } Q_{BE} = \frac{\$20 \text{ million}}{\$2.00 - \$1.50} = 40 \text{ million units}$$

$$\text{Plan U: } Q_{BE} = \frac{\$60 \text{ million}}{\$2.00 - \$1.00} = 60 \text{ million units}$$

Plan A will be profitable if unit sales are above 40 million, whereas Plan U requires sales of 60 million units before it is profitable. This difference occurs because Plan U has higher

FIGURE 15-2
Operating Leverage and Financial Leverage

fixed costs, so more units must be sold to cover these fixed costs. Panel A of Figure 15-2 illustrates the operating profitability of these two plans for different levels of unit sales. Because these companies have no debt, the return on assets and the return on equity measure operating profitability; we report ROE instead of ROA to facilitate comparisons when we discuss financial risk in the next section.

Suppose sales are at 80 million units. In this case, the ROE is identical for each plan. As unit sales begin to climb above 80 million, both plans increase in profitability, but ROE increases more for Plan U than for Plan A. If sales fall below 80 million, then both plans become less profitable, but ROE decreases more for Plan U than for Plan A. This illustrates that the combination of higher fixed costs and lower variable costs of Plan U magnifies its gain or loss relative to Plan A. In other words, because Plan U has higher operating leverage, it also has greater business risk.

15-2b Financial Risk and Financial Leverage

Financial risk is the additional risk placed on the common stockholders as a result of the decision to finance with debt.[2] Conceptually, stockholders face a certain amount of risk that is inherent in a firm's operations—this is its business risk, which is defined as the uncertainty in projections of future EBIT, NOPAT, and ROIC. If a firm uses debt (financial leverage), then the business risk is concentrated on the common stockholders.

[2]Preferred stock also adds to financial risk. To simplify matters, we examine only debt and common equity in this chapter.

To illustrate, suppose 10 people decide to form a corporation to manufacture flash memory drives. There is a certain amount of business risk in the operation. If the firm is capitalized only with common equity and if each person buys 10% of the stock, then each investor shares equally in the business risk. However, suppose the firm is capitalized with 50% debt and 50% equity, with five of the investors putting up their money by purchasing debt and the other five putting up their money by purchasing equity. In this case, the five debtholders are paid before the five stockholders, so *virtually all* of the business risk is borne by the stockholders. Thus, the use of debt, or **financial leverage**, concentrates business risk on stockholders.[3]

To illustrate the impact of financial risk, we can extend the Strasburg Electronics example. Strasburg initially decided to use the technology of Plan U, which is unlevered (financed with all equity), but now it's considering financing the technology with $150 million of equity and $50 million of debt at an 8% interest rate, as shown for Plan L in Figure 15-1 (recall that L denotes leverage). Section 3 shows that Plan L's NOPAT and ROIC are identical to those of Plan U—financing choices don't affect operations. However, Plan L has a lower ROA (13.7% versus 14.9%) and lower net income ($27.6 versus $30) because it must pay interest. Despite the lower net income, Plan L has a higher ROE (18.4% versus 15%) because the net income is shared by a smaller equity base.[4]

But there is more to the story than just a higher ROE with financial leverage. Just as operating leverage adds risk, so does financial leverage. We used the Data Table feature in the file ***Ch15 Tool Kit.xlsx*** to generate performance measures for plans U and L at different levels of unit sales. Panel B of Figure 15-2 shows the ROE of Plan L versus quantity sold.

When the quantity sold is 76 million, the crossover point in Panel B of Figure 15-2, both plans have an ROE and ROIC of 4.8%. (See the ***Tool Kit*** for the calculations.) The after-tax cost of debt also is $8\%(1 - 0.40) = 4.8\%$, which is no coincidence. As sales increase above 76 million units and ROIC increases above 4.8%, the ROE increases for each plan, but more for Plan L than for Plan U. However, if sales fall below 76 million units and ROIC falls below 4.8%, then the ROE falls further for Plan L than for Plan U. Thus, financial leverage magnifies the ROE for good or ill, depending on the ROIC, and so increases the risk of a levered firm relative to an unlevered firm.

We see, then, that using leverage has both good and bad effects: If expected ROIC is greater than the after-tax cost of debt, then higher leverage increases expected ROE but also increases risk.[5]

SELF-TEST

What is business risk, and how can it be measured?

What are some determinants of business risk?

How does operating leverage affect business risk?

What is financial risk, and how does it arise?

Explain this statement: "Using leverage has both good and bad effects."

A firm has fixed operating costs of $100,000 and variable costs of $4 per unit. If it sells the product for $6 per unit, what is the break-even quantity? **(50,000)**

[3]Holders of corporate debt generally do bear some business risk, because they may lose some of their investment if the firm goes bankrupt. We discuss this in more depth later in the chapter.

[4]Recall that Strasburg has $202 million in total assets, all of which are operating assets. With $2 million in operating current liabilities, Strasburg has $202 − $2 = $200 million in operating capital, which must be financed with a combination of debt and equity.

[5]It is possible to calculate measures of operating leverage, financial leverage, and total leverage as the percentage change in an output given a percentage change in an input. See ***Web Extension 15A*** for details.

15-3 Capital Structure Theory: The Modigliani and Miller Models

In the previous section, we showed how capital structure choices affect a firm's ROE and its risk. For a number of reasons, we would expect capital structures to vary considerably across industries. For example, pharmaceutical companies generally have very different capital structures than airline companies. Moreover, capital structures vary among firms within a given industry. What factors explain these differences? In an attempt to answer this question, academics and practitioners have developed a number of theories, and the theories have been subjected to many empirical tests. We discuss theories and empirical evidence in the following sections, beginning with the work of Professors Franco Modigliani and Merton Miller.[6]

15-3a Modigliani and Miller: No Taxes

Modern capital structure theory began in 1958, when Modigliani and Miller (hereafter, MM) published what has been called the most influential finance article ever written.[7] MM's study was based on some strong assumptions, which included the following:

1. There are no brokerage costs.
2. There are no taxes.
3. There are no bankruptcy costs.
4. Investors can borrow at the same rate as corporations.
5. All investors have the same information as management about the firm's future investment opportunities.
6. Earnings before interest and taxes (EBIT) do not grow and are not affected by the use of debt.

Modigliani and Miller imagined two hypothetical portfolios. The first contains all the equity of an unlevered firm, so the portfolio's value is V_U, the value of an unlevered firm. Because the firm has no growth (which means it does not need to invest in any new net assets) and because it pays no taxes, the firm can pay out all of its EBIT in the form of dividends. Therefore, the cash flow from owning this first portfolio is equal to EBIT.

Now consider a second firm that is identical to the unlevered firm *except* that it is partially financed with debt. The second portfolio contains all of the levered firm's stock (S_L) and debt (D), so the portfolio's value is V_L, the total value of the levered firm. If the interest rate is r_d, then the levered firm pays out interest in the amount r_dD. Because the firm is not growing and pays no taxes, it can pay out dividends in the amount $EBIT - r_dD$. If you owned all of the firm's debt and equity, your cash flow would be equal to the sum of the interest and dividends: $r_dD + (EBIT - r_dD) = EBIT$. Therefore, the cash flow from owning this second portfolio is equal to EBIT.

---

Notice that the cash flow of each portfolio is equal to EBIT. Thus, MM concluded that two portfolios producing the same cash flows must have the same value:[8]

$$V_L = V_U = S_L + D \quad \textbf{(15-5)}$$

Given their assumptions, MM proved that a firm's value is unaffected by its capital structure.[9] This result is often called the **MM Proposition I** without taxes.

MM assumed that debt doesn't affect EBIT and they prove that debt doesn't affect value. Therefore, debt doesn't affect the weighted average cost of capital (WACC). Recall that the WACC is a combination of the cost of debt and the relatively higher cost of equity, r_s. As leverage increases, more weight is given to low-cost debt but equity becomes riskier, which drives up r_s by exactly enough to keep the WACC constant.

MM showed that a constant WACC implies that the cost of equity to a levered firm, r_{sL}, is equal to:

$$r_{sL} = r_{sU} + (r_{sU} - r_d)(D/E) \quad \textbf{(15-6)}$$

Here r_{sU} is the cost of equity to an identical but unlevered firm, D is the market value of debt, S is the market value of equity, and r_d is the cost of debt (which is assumed to be constant for all degrees of leverage). Equation 15-6 is called the **MM Proposition II** without taxes.

Taken together, the two MM propositions imply that using more debt in the capital structure will not increase the value of the firm, because the benefits of cheaper debt will be exactly offset by an increase in the riskiness of the equity and hence in its cost. Thus, MM argued that, *in a world without taxes, both the value of a firm and its WACC would be unaffected by its capital structure.*

Even though some of their assumptions are obviously unrealistic, MM's irrelevance result is extremely important. By indicating the conditions under which capital structure is irrelevant, MM also provided us with clues about what is required for capital structure to be relevant and hence to affect a firm's value. The work of MM marked the beginning of modern capital structure research, and subsequent research has focused on relaxing the MM assumptions in order to develop a more realistic theory of capital structure.

Modigliani and Miller's thought process was just as important as their conclusion. It seems simple now, but their idea that two portfolios with identical cash flows must also have identical values changed the entire financial world because it led to the development of options and derivatives. It is no surprise that Modigliani and Miller received Nobel awards for their work.

[8]They actually showed that if the values of the two portfolios differed, then an investor could engage in riskless arbitrage: The investor could create a trading strategy (buying one portfolio and selling the other short) that had no risk, required none of the investor's own cash, and resulted in a positive cash flow for the investor. This would be such a desirable strategy that everyone would try to implement it. But if everyone tries to buy the same portfolio, its price will be driven up by market demand, and if everyone tries to short sell a portfolio, its price will be driven down. The net result of the trading activity would be to change the portfolios' values until they were equal and no more arbitrage was possible.

[9]See ***Web Extension 15B*** for a more formal derivation of this result and for derivations of the other MM and Miller models.

15-3b Modigliani and Miller: The Effect of Corporate Taxes

In 1963, MM published a follow-up paper in which they relaxed the assumption that there are no corporate taxes.[10] The Tax Code allows corporations to deduct interest payments as an expense, but dividend payments to stockholders are not deductible. The differential treatment encourages corporations to use debt in their capital structures. This means that interest payments reduce the taxes a corporation pays, and if a corporation pays less to the government, then more of its cash flow is available for investors. In other words, the tax deductibility of the interest payments shields the firm's pre-tax income.

To illustrate, look at Figure 15-1 and see that Plan U (with no debt) pays taxes of $20, but Plan L (with leverage) pays taxes of only $18.40. What happens to the difference of $1.60 = $20 − $18.40? This extra amount is paid out to investors! Notice that Plan U has $30 of net income for shareholders, but Plan L has $4 of interest for debtholders and $27.60 of net income for shareholders for a combined total of $31.60, which is exactly $1.60 more than Plan U. With more cash flows available for investors, a levered firm's total value should be greater than that of an unlevered firm, and this is what MM showed.

As in their earlier paper, MM introduced a second important way of looking at the effect of capital structure: The value of a levered firm is the value of an otherwise identical unlevered firm plus the value of any "side effects." While others have expanded on this idea by considering other side effects, MM focused on the tax shield:

$$V_L = V_U + \text{Value of side effects} = V_U + \text{Present value of tax shield} \quad \textbf{(15-7)}$$

Under their assumptions, they showed that the present value of the tax shield is equal to the corporate tax rate, T, multiplied by the amount of debt, D:

$$V_L = V_U + TD \quad \textbf{(15-8)}$$

Yogi Berra on the MM Proposition

When a waitress asked Yogi Berra, Baseball Hall of Fame catcher for the New York Yankees, whether he wanted his pizza cut into four pieces or eight, Yogi replied: "Better make it four. I don't think I can eat eight."[a]

Yogi's quip helps convey the basic insight of Modigliani and Miller. The firm's choice of leverage "slices" the distribution of future cash flows in a way that is like slicing a pizza. MM recognized that holding a company's investment activities fixed is like fixing the size of the pizza; no information costs means that everyone sees the same pizza; no taxes means the IRS gets none of the pie; and no "contracting costs" means nothing sticks to the knife.

So, just as the substance of Yogi's meal is unaffected by whether the pizza is sliced into four pieces or eight, the economic substance of the firm is unaffected by whether the liability side of the balance sheet is sliced to include more or less debt—at least under the MM assumptions.

This is the MM Proposition I with corporate taxes. With a tax rate of about 40%, this implies that every dollar of debt adds about 40 cents of value to the firm, and this leads to the conclusion that the optimal capital structure is virtually 100% debt.

MM also showed that the WACC falls as debt is added. This is because the cost of equity, r_s, doesn't increase quite as fast as it would if there were no taxes. Equation 15-9 is a version of Proposition II with corporate taxes included:

$$r_{sL} = r_{sU} + (r_{sU} - r_d)(1 - T)(D/S) \quad \textbf{(15-9)}$$

15-3c Miller: The Effect of Corporate and Personal Taxes

Merton Miller (this time without Modigliani) later brought in the effects of personal taxes.[11] The income from bonds is generally interest, which is taxed as personal income at rates (T_d) going up to 39.6%, while income from stocks generally comes partly from dividends and partly from capital gains. Long-term capital gains are taxed at a rate of 20%, and this tax is deferred until the stock is sold and the gain realized. If stock is held until the owner dies, no capital gains tax whatsoever must be paid. So, on average, returns on stocks are taxed at lower effective rates (T_s) than returns on debt.[12]

Because of the tax situation, Miller argued that investors are willing to accept relatively low before-tax returns on stock relative to the before-tax returns on bonds. (The situation here is similar to that with tax-exempt municipal bonds, discussed in Chapter 5, and preferred stocks held by corporate investors, discussed in Chapter 7.) For example, an investor might require a return of 10% on Strasburg's bonds, and if stock income were taxed at the same rate as bond income, the required rate of return on Strasburg's stock might be 16% because of the stock's greater risk. However, in view of the favorable treatment of income on the stock, investors might be willing to accept a before-tax return of only 14% on the stock.

Thus, as Miller pointed out, the tax code has two opposite implications. First, the *corporate deductibility of interest* favors the use of debt financing. Second, the *more favorable personal tax treatment of income from stock* lowers the required rate of return on stock and thus favors the use of equity financing.

Miller showed that the net impact of corporate and personal taxes is given by this equation, which is called the **Miller model**:

$$V_L = V_U + \left[1 - \frac{(1 - T_c)(1 - T_s)}{(1 - T_d)}\right] D \quad \textbf{(15-10)}$$

Here T_c is the corporate tax rate, T_s is the personal tax rate on income from stocks, and T_d is the tax rate on income from debt. Miller argued that the marginal tax rates on stock and debt balance out in such a way that the bracketed term in Equation 15-8 is zero

[11]See Merton H. Miller, "Debt and Taxes," *Journal of Finance,* May 1977, pp. 261–275.

[12]The Tax Code isn't quite as simple as this. An increasing number of investors face the Alternative Minimum Tax (AMT); see ***Web Extension 2A*** for a discussion. The AMT imposes a 28% tax rate on most income and an effective rate of 22% on long-term capital gains and dividends. Under the AMT there is still a spread between the tax rates on interest income and stock income, but the spread is narrower. See Leonard Burman, William Gale, Greg Leiserson, and Jeffrey Rohaly, "The AMT: What's Wrong and How to Fix It," *National Tax Journal*, September 2007, pp. 385–405.

and so $V_L = V_U$, but most observers believe there is still a tax advantage to debt if reasonable values of tax rates are assumed. For example, if the marginal corporate tax rate is 40%, the marginal rate on debt is 30%, and the marginal rate on stock is 12%, then the advantage of debt financing is:

$$V_L = V_U + \left[1 - \frac{(1 - 0.40)(1 - 0.12)}{(1 - 0.30)}\right]D \quad \textbf{(15-10a)}$$
$$= V_U + 0.25D$$

Thus it appears that the presence of personal taxes reduces but does not completely eliminate the advantage of debt financing.

The Miller model has several important implications, as follows.

1. The bracketed term in Equation 15-10,
$$\left[1 - \frac{(1 - T_c)(1 - T_s)}{(1 - T_d)}\right]$$
when multiplied by D, represents the gain from leverage. The bracketed term thus replaces the corporate tax rate, T, in the earlier MM model with corporate taxes: $V_L = V_U + TD$.
2. If we ignore all taxes (i.e., if $T_c = T_s = T_d = 0$), then the bracketed term is zero, so in this case Equation 15-10 is the same as the original MM model without taxes.
3. If we ignore personal taxes (i.e., if $T_s = T_d = 0$), then the bracketed term reduces to $[1 - (1 - T_c)] = T_c$, so in this case Equation 15-10 is the same as the MM model with corporate taxes.
4. If the effective personal tax rates on stock and bond incomes were equal (i.e., if $T_s = T_d$), then $(1 - T_s)$ and $(1 - T_d)$ would cancel and so the bracketed term would again reduce to T_c.
5. If $(1 - T_c)(1 - T_s) = (1 - T_d)$, then the bracketed term would be zero, and so the value of using leverage would also be zero. This implies that the tax advantage of debt to the firm would be exactly offset by the personal tax advantage of equity. Under this condition, capital structure would have no effect on a firm's value or its cost of capital, so we would be back to MM's original zero-tax proposition.

SELF-TEST

What does the MM theory with no taxes state about the value of a levered firm versus the value of an otherwise identical but unlevered firm? What does this imply about the optimal capital structure?

Why does the MM theory with corporate taxes lead to 100% debt?

What does the Miller model with personal and corporate taxes imply about value relative to the MM model with just corporate taxes?

15-4 Capital Structure Theory: Beyond the Modigliani and Miller Models

The MM's models are important because they guided subsequent research in terms of methodology: Compare levered firms with unlevered firms and look for side effects. Also, the unrealistic MM assumptions provided a place for subsequent researchers to extend the

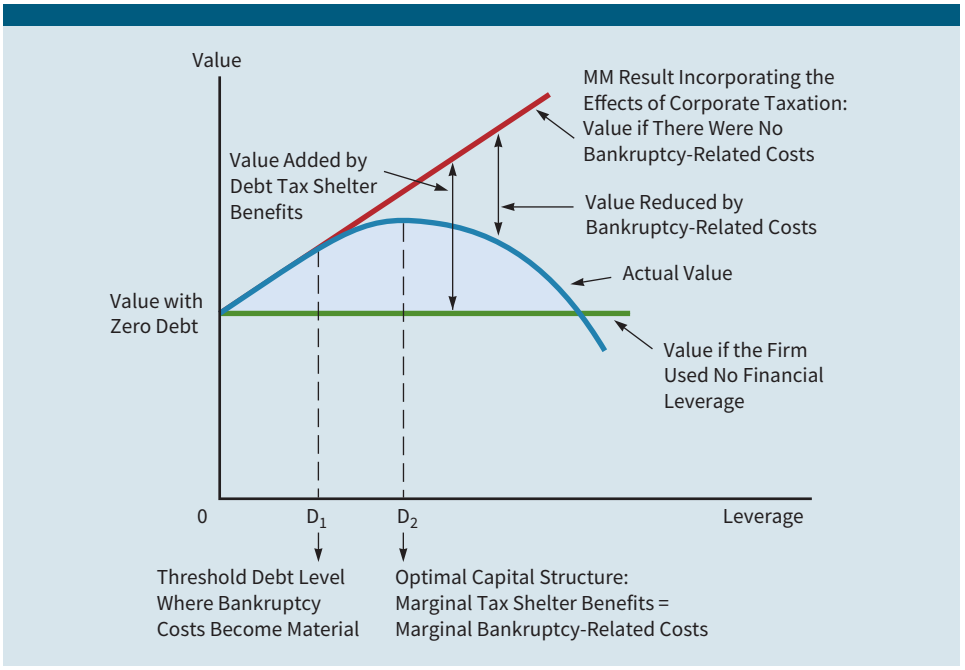
MM models by relaxing the assumptions. The following sections describe the important developments in capital structure theory.

15-4a Trade-Off Theory

The results of Modigliani and Miller also depend on the assumption that there are no **bankruptcy costs**. However, bankruptcy can be quite costly. Firms in bankruptcy have very high legal and accounting expenses, and they also have a hard time retaining customers, suppliers, and employees. Moreover, bankruptcy often forces a firm to liquidate or sell assets for less than they would be worth if the firm were to continue operating. For example, if a steel manufacturer goes out of business, it might be hard to find buyers for the company's blast furnaces. Such assets are often illiquid because they are configured to a company's individual needs and also because they are difficult to disassemble and move.

Note, too, that the *threat of bankruptcy,* not just bankruptcy per se, causes **financial distress costs**. Key employees jump ship, suppliers refuse to grant credit, customers seek more stable suppliers, and lenders demand higher interest rates and impose more restrictive loan covenants if potential bankruptcy looms. Therefore, even the threat of bankruptcy can cause free cash flows to fall, causing further declines in a company's value.

Bankruptcy-related problems are most likely to arise when a firm includes a great deal of debt in its capital structure. Therefore, bankruptcy costs discourage firms from pushing their use of debt to excessive levels.



Bankruptcy-related costs have two components: (1) the probability of financial distress and (2) the costs that would be incurred if financial distress does occur. Firms whose earnings are more volatile, all else equal, face a greater chance of bankruptcy and should therefore use less debt than more stable firms. This is consistent with our earlier point that firms with high operating leverage, and thus greater business risk, should limit their use of financial leverage. Likewise, firms that would face high costs in the event of financial distress should rely less heavily on debt. For example, firms whose assets are illiquid and thus would have to be sold at "fire sale" prices should limit their use of debt financing.

The preceding arguments led to the development of what is called the trade-off theory of leverage, in which firms trade off the benefits of debt financing (favorable corporate tax treatment) against higher interest rates and bankruptcy costs. In essence, the **trade-off theory** says that the value of a levered firm is equal to the value of an unlevered firm plus the value of any side effects, which include the tax shield and the expected costs due to financial distress. A summary of the trade-off theory is expressed graphically in Figure 15-3, and a list of observations about the figure follows here.

1. Under the assumptions of the MM model with corporate taxes, a firm's value increases linearly for every dollar of debt. The line labeled "MM Result Incorporating the Effects of Corporate Taxation" in Figure 15-3 expresses the relationship between value and debt under those assumptions.
2. There is some threshold level of debt, labeled D_1 in Figure 15-3, below which the probability of bankruptcy is so low as to be immaterial. Beyond D_1, however, expected bankruptcy-related costs become increasingly important, and they reduce the tax benefits of debt at an increasing rate. In the range from D_1 to D_2, expected bankruptcy-related costs reduce but do not completely offset the tax benefits of debt, so the stock price rises (but at a decreasing rate) as the debt ratio increases. However, beyond D_2, expected bankruptcy-related costs exceed the tax benefits, so from this point on increasing the debt ratio lowers the value of the stock. Therefore, D_2 is the

FIGURE 15-3
Effect of Financial Leverage on Value

optimal capital structure. Of course, D_1 and D_2 vary from firm to firm, depending on their business risks and bankruptcy costs.

3. Although theoretical and empirical work confirms the general shape of the curve in Figure 15-3, this graph must be taken as an approximation and not as a precisely defined function.

15-4b Signaling Theory

MM assumed that investors have the same information about a firm's prospects as its managers—this is called **symmetric information**. However, managers in fact often have better information than outside investors. This is called **asymmetric information**, and it has an important effect on the optimal capital structure. To see why, consider two situations, one in which the company's managers know that its prospects are extremely positive (Firm P) and one in which the managers know that the future looks negative (Firm N).

Suppose, for example, that Firm P's R&D labs have just discovered a cure for the common cold. Firm P can't provide investors with any details about the product because that might give competitors an advantage. But if they don't provide details, then investors will underestimate the value of the discovery. Given the inability to provide accurate, verifiable information to the market, how should Firm P's management raise the needed capital?

Suppose Firm P issues stock. When profits from the new product start flowing in, the price of the stock would rise sharply and the purchasers of the new stock would make a bonanza. The current stockholders (including the managers) would also do well, but not as well as they would have done if the company had not sold stock before the price increased, because then they would not have had to share the benefits of the new product with the new stockholders. Therefore, *we should expect a firm with very positive prospects*

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. to avoid selling stock and instead to raise required new capital by other means, including debt usage beyond the normal target capital structure.[13]

Now let's consider Firm N. Suppose its managers have information that new orders are off sharply because a competitor has installed new technology that has improved its products' quality. Firm N must upgrade its own facilities, at a high cost, just to maintain its current sales. As a result, its return on investment will fall (but not by as much as if it took no action, which would lead to a 100% loss through bankruptcy). How should Firm N raise the needed capital? Here the situation is just the reverse of that facing Firm P, which did not want to sell stock so as to avoid having to share the benefits of future developments. *A firm with negative prospects would want to sell stock, which would mean bringing in new investors to share the losses!*[14] The conclusion from all this is that firms with extremely bright prospects prefer not to finance through new stock offerings, whereas firms with poor prospects like to finance with outside equity. How should you, as an investor, react to this conclusion? You ought to say: "If I see that a company plans to issue new stock, this should worry me because I know that management would not want to issue stock if future prospects looked good. However, management *would* want to issue stock if things looked bad. Therefore, I should lower my estimate of the firm's value, other things held constant, if it plans to issue new stock."

If you gave this answer, then your views are consistent with those of sophisticated portfolio managers. In a nutshell: *The announcement of a stock offering is generally taken as a signal that the firm's prospects as seen by its own management are not good.* This is the essence of the capital structure **signaling theory**, which suggests that firms should issue debt rather than stock. Notice that Firm N's managers cannot make a false signal to investors by mimicking Firm P and issuing debt. With its unfavorable future prospects, issuing debt could soon force Firm N into bankruptcy. Given the resulting damage to the personal wealth and reputations of N's managers, they cannot afford to mimic Firm P. All of this suggests that when a firm announces a new stock offering, more often than not the price of its stock will decline. Empirical studies have shown that this is indeed true.

15-4c Reserve Borrowing Capacity

Because issuing stock sends a negative signal and tends to depress the stock price even if the company's true prospects are bright, a company should try to maintain a **reserve borrowing capacity** so that debt can be used if an especially good investment opportunity comes along. This means that *firms should, in normal times, use more equity and less debt than is suggested by the tax benefit–bankruptcy cost trade-off model depicted in Figure 15-3.*

15-4d The Pecking Order Hypothesis

The presence of flotation costs and asymmetric information may cause a firm to raise capital according to a **pecking order**. In this situation, a firm first raises capital internally by reinvesting its net income and selling its short-term marketable securities. When that

[13]It would be illegal for Firm P's managers to personally purchase more shares on the basis of their inside knowledge of the new product.

[14]Of course, Firm N would have to make certain disclosures when it offered new shares to the public, but it might be able to meet the legal requirements without fully disclosing management's worst fears.

supply of funds has been exhausted, the firm will issue debt and perhaps preferred stock. Only as a last resort will the firm issue common stock.[15]

15-4e Using Debt Financing to Constrain Managers

Agency problems may arise if managers and shareholders have different objectives. Such conflicts are particularly likely when the firm's managers have too much cash at their disposal. Managers often use excess cash to finance pet projects or for perquisites such as nicer offices, corporate jets, and skyboxes at sports arenas—none of which have much to do with maximizing stock prices. Even worse, managers might be tempted to pay too much for an acquisition, something that could cost shareholders hundreds of millions of dollars. By contrast, managers with limited "excess cash flow" are less able to make wasteful expenditures.

Firms can reduce excess cash flow in a variety of ways. One way is to funnel some of it back to shareholders through higher dividends or stock repurchases. Another alternative is to shift the capital structure toward more debt in the hope that higher debt service requirements will force managers to be more disciplined. If debt is not serviced as required, then the firm will be forced into bankruptcy, in which case its managers would likely lose their jobs. Therefore, a manager is less likely to buy an expensive new corporate jet if the firm has large debt service requirements that could cost the manager his or her job. In short, high levels of debt *bond the cash flow*, because much of it is precommitted to servicing the debt.

A **leveraged buyout (LBO)** is one way to bond cash flow. In an LBO, a large amount of debt and a small amount of cash are used to finance the purchase of a company's shares, after which the firm "goes private." The first wave of LBOs was in the mid-1980s; private equity funds led the buyouts of the late 1990s and early 2000s. Many of these LBOs were specifically designed to reduce corporate waste. As noted, high debt payments force managers to conserve cash by eliminating unnecessary expenditures.

Of course, increasing debt and reducing the available cash flow has its downside: It increases the risk of bankruptcy. Ben Bernanke, former chairman of the Fed, has argued that adding debt to a firm's capital structure is like putting a dagger into the steering wheel of a car.[16] The dagger—which points toward your stomach—motivates you to drive more carefully, but you may get stabbed if someone runs into you—even if you are being careful. The analogy applies to corporations in the following sense: Higher debt forces managers to be more careful with shareholders' money, but even well-run firms could face bankruptcy (get stabbed) if some event beyond their control occurs: a war, an earthquake, a strike, or a recession. To complete the analogy, the capital structure decision comes down to deciding how long a dagger stockholders should use to keep managers in line.

Finally, too much debt may overly constrain managers. A large portion of a manager's personal wealth and reputation is tied to a single company, so managers are not well diversified. When faced with a positive-NPV project that is risky, a manager may decide that it's not worth taking on the risk even though well-diversified stockholders would find the risk acceptable. The more debt the firm has, the greater the likelihood of financial distress and thus the greater the likelihood that managers will forgo risky projects even if they have positive NPVs. This is called the **underinvestment problem**.

15-4f The Investment Opportunity Set and Reserve Borrowing Capacity

Bankruptcy and financial distress are costly, and, as just reiterated, this can discourage highly levered firms from undertaking risky new investments. If potential new investments, although risky, have positive net present values, then high levels of debt can be doubly costly—the expected financial distress and bankruptcy costs are high, and the firm loses potential value by not making some potentially profitable investments. On the other hand, if a firm has very few profitable investment opportunities, then high levels of debt can keep managers from wasting money by investing in poor projects. For such companies, increases in the debt ratio can actually increase the value of the firm.

Thus, in addition to the tax, signaling, bankruptcy, and managerial constraint effects discussed previously, the firm's optimal capital structure is related to its set of investment opportunities. Firms with many profitable opportunities should maintain their ability to invest by using low levels of debt, which is also consistent with maintaining reserve borrowing capacity. Firms with few profitable investment opportunities should use high levels of debt (which have high interest payments) to impose managerial constraint.[17]

15-4g The Market Timing Theory

If markets are efficient, then security prices should reflect all available information; hence, they are neither underpriced nor overpriced (except during the time it takes prices to move to a new equilibrium caused by the release of new information). The *market timing theory* states that managers don't believe this and supposes instead that stock prices and interest rates are sometimes either too low or too high relative to their true fundamental values. In particular, the theory suggests that managers issue equity when they believe stock market prices are abnormally high and issue debt when they believe interest rates are abnormally low. In other words, they try to time the market.[18] Notice that this differs from signaling theory because no asymmetric information is involved. These managers aren't basing their beliefs on insider information, just on a different opinion than the market consensus.

SELF-TEST

Explain how asymmetric information *and* signals *affect capital structure decisions.*

What is meant by reserve borrowing capacity, *and why is it important to firms?*

How can the use of debt serve to discipline managers?

15-5 Capital Structure Evidence and Implications

As the previous sections show, there are a lot of capital structure theories! Which ones are correct and which ones are important for managers? As we show in the following sections, each of the theories provides useful insights and guidelines for managers making capital structure decisions.

[17]See Michael J. Barclay and Clifford W. Smith, Jr., "The Capital Structure Puzzle: Another Look at the Evidence," *Journal of Applied Corporate Finance,* Spring 1999, pp. 8–20.

[18]See Malcolm Baker and Jeffrey Wurgler, "Market Timing and Capital Structure," *Journal of Finance,* February 2002, pp. 1–32.

15-5a Empirical Evidence[19]

There have been hundreds, perhaps even thousands, of papers testing the capital structure theories described in the previous section. We can cover only the highlights here, beginning with the empirical evidence.[20]

THE TRADE-OFF BETWEEN TAX BENEFITS AND BANKRUPTCY COSTS

Recent studies by Professors Van Binsbergen, Graham, and Yang and by Professor Korteweg suggest that the average net benefits of leverage (i.e., the value of the tax shield less the expected cost of financial distress) make up about 3% to 6% of a levered firm's value.[21] To put this into perspective, let's look at the impact of debt on an average company's value. The average company is financed with about 25% to 35% debt, so let's suppose that the company has $25 of debt and $75 of equity, just to keep the arithmetic simple. The total net benefit of debt is about $5, based on the recent research. This implies that each dollar of debt added (on average) about $0.20 of value ($\$5/\$25 = 0.2$) to the company. The first dollar of debt adds a bigger net benefit because bankruptcy risk is low when debt is low. By the time the 25th dollar of debt is added, its incremental net benefit is close to zero—the incremental expected costs of financial distress are about equal to the incremental expected tax shield.

These studies also showed that the net benefits of debt increase slowly until reaching the optimal level but decline rapidly thereafter. In other words, it isn't very costly to be somewhat below the optimal level of debt, but it is costly to exceed it.

A particularly interesting study by Professors Mehotra, Mikkelson, and Partch examined the capital structure of firms that were spun off from their parent companies.[22] The financing choices of existing firms might be influenced by their past financing choices and by the costs of moving from one capital structure to another, but because spin-offs are newly created companies, managers can choose a capital structure without regard to these issues. The study found that more profitable firms (which have a lower expected probability of bankruptcy) and more asset-intensive firms (which have better collateral and thus a lower cost of bankruptcy should one occur) have higher levels of debt.

The Miller model hypothesizes that the value of a levered firm is affected by personal tax rates as well as corporate tax rates. Therefore, a cut in the tax rate on dividends should reduce the value of leverage, all else held equal. Professors Lin and Flannery examined the 2003 tax cut on dividends and found that leverage decreases as the personal effective tax rate on stock decreases, which is consistent with the Miller model's prediction. In addition, the impact of the tax cut was more pronounced for companies with a high proportion of individual owners (who are subject to personal income tax) than for companies with a high proportion of institutional owners (such as pension funds that might not be liable for personal taxes).[23]

---

[19]All of the empirical results described in this section are based on market values of leverage, not book values.

[20]This section also draws heavily from Barclay and Smith, "The Capital Structure Puzzle," cited in footnote 17; Jay Ritter, ed., *Recent Developments in Corporate Finance* (Northampton, MA: Edward Elgar Publishing Inc., 2005); and a presentation by Jay Ritter at the 2003 FMA meeting, "The Windows of Opportunity Theory of Capital Structure."

The empirical evidence clearly shows that corporate taxes, personal taxes, and bankruptcy costs matter when it comes to choosing a capital structure. In particular, companies do consider the trade-off between tax benefits and bankruptcy costs.

A DYNAMIC TRADE-OFF THEORY

However, there is also evidence that is inconsistent with the static optimal target capital structure implied by the trade-off theory. For example, stock prices are volatile, which frequently causes a firm's actual market-based debt ratio to deviate from its target. However, such deviations don't cause firms to immediately return to their target by issuing or repurchasing securities. Instead, Professors Flannery and Rangan show that firms tend to make a partial adjustment each year, moving about 30% of the way toward their target capital structure. In a more recent study, Professors Faulkender, Flannery, Hankins, and Smith show that the speed of adjustment depends on a company's cash flows—companies with high cash flows adjust by about 50%. This effect is even more pronounced if the company's leverage exceeds its target—high cash flow companies in this situation have a 70% speed of adjustment. This is consistent with the idea that it is more costly to exceed the target debt ratio than to be lower than the target.[24]

MARKET TIMING

As we mentioned in Chapter 14, companies with infrequent stock repurchase activity are able to repurchase stock at a lower average price than the average price in the months surrounding the repurchase, indicating ability to time the market with respect to repurchases. This supports the idea that a firm's managers have better information than investors regarding their stock's value, implying that managers would issue stock when it is overvalued. We see evidence of this when a company has had a big stock run-up. This reduces the market-based leverage ratio, so the trade-off theory suggests that the firm should issue debt to return to its target. However, firms tend to do the opposite, issuing stock after big run-ups. This is much more consistent with the market timing theory, with managers trying to time the market by issuing stock when they perceive the market to be overvalued.

Furthermore, firms tend to issue debt when stock prices and interest rates are low. The maturity of the issued debt seems to reflect an attempt to time interest rates: Firms tend to issue short-term debt if the term structure is upward sloping but long-term debt if the term structure is flat. Again, these facts suggest that managers try to time the market.

SIGNALING AND THE PECKING ORDER

When a firm announces a seasoned equity offering, the stock price tends to fall by around 2% to 4%, all else held equal, suggesting that investors believe that firms issue equity when it is overvalued.[25] For seasoned nonconvertible debt offerings, the stock price tends to fall a little, but not by a significant amount.[26] Asymmetric information is a significant problem in stock and bond issues, but is less likely when a company announces a large

credit agreement with a bank—in fact, the stock price reaction is positive.[27] These results suggest that signaling is important, especially when informational asymmetry is high.

Given these results, it is no surprise that firms issue equity much less frequently than debt. On the surface, this seems to support both the pecking order hypothesis and the signaling hypothesis. The pecking order hypothesis predicts that firms with a high level of informational asymmetry, which causes equity issuances to be costly, should issue debt before issuing equity. Yet we often see the opposite, with high-growth firms (which usually have greater informational asymmetry) issuing more equity than debt. Also, many highly profitable firms could afford to issue debt (which comes before equity in the pecking order) but instead choose to issue equity. With respect to the signaling hypothesis, consider the case of firms that have large increases in earnings that were unanticipated by the market. If managers have superior information, then they will anticipate these upcoming performance improvements and issue debt before the increase. Such firms do, in fact, tend to issue debt slightly more frequently than other firms, but the difference isn't economically meaningful.

RESERVE BORROWING CAPACITY

Many firms have less debt than might be expected, and many have large amounts of short-term investments. This is especially true for firms with high market/book ratios (which indicate many growth options as well as informational asymmetry). This behavior is consistent with the hypothesis that investment opportunities influence attempts to maintain reserve borrowing capacity. It is also consistent with tax considerations, because low-growth firms (which have more debt) are more likely to benefit from the tax shield. This behavior is not consistent with the pecking order hypothesis, where low-growth firms (which often have high free cash flow) would be able to avoid issuing debt by raising funds internally.

SUMMARY OF EMPIRICAL TESTS

To summarize these results, it appears that firms try to capture debt's tax benefits while avoiding financial distress costs. However, they also allow their debt ratios to deviate from the static optimal target ratio implied by the trade-off theory. In fact, Professors Harry DeAngelo, Linda DeAngelo, and Toni Whited extend the dynamic trade-off model by showing that firms often deliberately issue debt to take advantage of unexpected investment opportunities, even if this causes them to exceed their target debt ratio.[28] Firms often maintain reserve borrowing capacity, especially firms with many growth opportunities or problems with informational asymmetry.[29] There is a little evidence indicating that firms follow a pecking order and use security issuances as signals, but there is some evidence in support of the market timing theory.

15-5b Implications for Managers

Managers should explicitly consider tax benefits when making capital structure decisions. Tax benefits obviously are more valuable for firms with high tax rates. Firms can utilize tax loss carryforwards and carrybacks, but the time value of money means that tax benefits are more valuable for firms with stable, positive pre-tax income. Therefore, a firm whose sales are relatively stable can safely take on more debt and incur higher fixed charges than a company with volatile sales. Other things being equal, a firm with less operating leverage is better able to employ financial leverage because it will have less business risk and less volatile earnings.

Managers should also consider the expected cost of financial distress, which depends on the probability and cost of distress. Notice that stable sales and lower operating leverage provide tax benefits but also reduce the *probability* of financial distress. One *cost* of financial distress comes from lost investment opportunities. Firms with profitable investment opportunities need to be able to fund them, either by holding higher levels of marketable securities or by maintaining excess borrowing capacity.

Another cost of financial distress is the possibility of being forced to sell assets to meet liquidity needs. General-purpose assets that can be used by many businesses are relatively liquid and make good collateral, in contrast to special-purpose assets. Thus, real estate companies are usually highly leveraged, whereas companies involved in technological research are not.

Asymmetric information also has a bearing on capital structure decisions. For example, suppose a firm has just successfully completed an R&D program, and it forecasts higher earnings in the immediate future. However, the new earnings are not yet anticipated by investors and hence are not reflected in the stock price. This company should not issue stock—it should finance with debt until the higher earnings materialize and are reflected in the stock price. Then it could issue common stock, retire the debt, and return to its target capital structure.

Managers should consider conditions in the stock and bond markets. For example, during a recent credit crunch, the junk bond market dried up and there was simply no market at a "reasonable" interest rate for any new long-term bonds rated below BBB. Therefore, low-rated companies in need of capital were forced to go to the stock market or to the short-term debt market, regardless of their target capital structures. When conditions eased, however, these companies sold bonds to get their capital structures back on target.

Finally, managers should always consider lenders' and rating agencies' attitudes. For example, Moody's and Standard & Poor's told a large utility that its bonds would be downgraded if it issued more debt. This influenced the utility's decision to finance its expansion with common equity. This doesn't mean that managers should never increase debt if it will cause their bond rating to fall, but managers should always factor this into their decision making.[30]

SELF-TEST

Which capital structure theories does the empirical evidence seem to support?

What issues should managers consider when making capital structure decisions?

[30]For some insights into how practicing financial managers view the capital structure decision, see John Graham and Campbell Harvey, "The Theory and Practice of Corporate Finance: Evidence from the Field," *Journal of Financial Economics,* Vol. 60, 2001, pp. 187–243; Ravindra R. Kamath, "Long-Term Financing Decisions: Views and Practices of Financial Managers of NYSE Firms," *Financial Review,* May 1997, pp. 331–356; and Edgar Norton, "Factors Affecting Capital Structure Decisions," *Financial Review,* August 1991, pp. 431–446.

15-6 Estimating the Optimal Capital Structure

Managers should choose the capital structure that maximizes shareholders' wealth. The basic approach is to consider a trial capital structure, based on the market values of the debt and equity, and then estimate the wealth of the shareholders under this capital structure. This approach should be repeated until an optimal capital structure is identified. There are several steps in the analysis of each potential capital structure: (1) Estimate the interest rate the firm will pay. (2) Estimate the cost of equity. (3) Estimate the weighted average cost of capital. (4) Estimate the value of operations, which is the present value of free cash flows discounted by the new WACC. The objective is to find the amount of debt financing that maximizes the value of operations. As we will show, this capital structure maximizes both shareholder wealth and the intrinsic stock price. The following sections explain each of these steps, using the company we considered earlier, Strasburg Electronics.

15-6a Strasburg's Current Value and Capital Structure

In Section 15-2, Strasburg was examining several different capital structure plans. Strasburg implemented Plan L, the one with high operating leverage and \$50 million in debt financing. The plan has been in place for a year, and Strasburg's stock price is now \$20 per share. With 10 million shares, Strasburg's market value of equity is $\$20(10) = \$200$ million. Strasburg has no short-term investments, so Strasburg's total enterprise value is the sum of its debt and equity: $V = \$50 + \$200 = \$250$ million. In terms of market values, Strasburg's capital structure has 20% debt ($w_d = \$50/\$250 = 0.20$) and 80% equity ($w_s = \$200/\$250 = 0.80$). These calculations are reported in Figure 15-4 along with other input data.

Is this the optimal capital structure? We will address the question in more detail later, but for now let's focus on understanding Strasburg's current valuation, beginning with its cost of capital. Strasburg has a beta of 1.25. We can use the Capital Asset Pricing Model (CAPM) to estimate the cost of equity. The risk-free rate, r_{RF}, is 6.3% and the market risk premium, RP_M, is 6%, so the cost of equity is:

$$r_s = r_{RF} + b(RP_M) = 6.3\% + 1.25(6\%) = 13.8\%$$

The weighted average cost of capital is:

$$\begin{aligned} WACC &= w_d(1 - T)r_d + w_s r_s \\ &= 20\%(1 - 0.40)(8\%) + 80\%(13.8\%) \\ &= 12\% \end{aligned}$$

As shown previously in Figure 15-1, Plan L has a NOPAT of \$30 million. Strasburg expects zero growth, which means there are no required investments in capital. Therefore, FCF is equal to NOPAT, as shown in Figure 15-4. Using the constant growth formula, the value of operations is:

$$V_{op} = \frac{FCF(1 + g_L)}{WACC - g_L} = \frac{\$30(1 + 0)}{0.12 - 0} = \$250$$

Figure 15-4 illustrates the calculation of the intrinsic stock price. For Strasburg, the intrinsic stock price and the market price are each equal to \$20. Can Strasburg increase its value by changing its capital structure? The next sections answer that question.

FIGURE 15-4
Strasburg's Current Value and Capital Structure (Millions of Dollars, Except for Per Share Data)

	A	B	C	D	E
98	**Input Data:**		**Capital Structure:**		
99	Tax rate	40.00%	Market value of equity (S = P x n)		$200
100	Debt (D)	$50.00	Total value (V = D + S)		$250
101	# of shares (n)	10.00	% financed with debt (w_d = D/V)		20%
102	Stock price (P)	$20.00	% financed with stock (w_s = S/V)		80%
103	NOPAT	$30.00			
104	Free Cash Flow (FCF)	$30.00			
105	Growth rate in FCF (g_L)	0.00%			
106	**Cost of Capital:**		**Estimated Intrinsic Value:**		
107	Cost of debt (r_d)	8.00%	Value of operations:		
108	Beta (b)	1.25	$V_{op} = [FCF(1 + g_L)]/(WACC \quad g_L)$		$250.00
109	Risk-free rate (r_{RF})	6.30%	+ Value of ST investments		$0.00
110	Mkt. risk prem. (RP_M)	6.00%	Estimated total intrinsic value		$250.00
111	Cost of equity:		Debt		$50.00
112	$r_s = r_{RF} + b(RP_M)$	13.80%	Estimated intrinsic value of equity		$200.00
113	WACC	12.00%	÷ Number of shares		10.00
114			Estimated intrinsic price per share		$20.00

Source: See the file ***Ch15 Tool Kit.xlsx***. Numbers are reported as rounded values for clarity, but are calculated using *Excel*'s full precision. Thus, intermediate calculations using the figure's rounded values will be inexact.

Note: Strasburg's sales, earnings, and assets are not growing, so it does not need investments in operating capital. Therefore, FCF = NOPAT(1 − T). The growth in FCF also is zero.

15-6b Estimating the Weighted Average Cost of Capital (WACC) for Different Levels of Debt

Following is a description of the steps to estimate the weighted average cost of capital for different levels of debt.

ESTIMATING THE COST OF DEBT (r_d)

The CFO asked Strasburg's investment bankers to estimate the cost of debt at different capital structures. The investment bankers began by analyzing industry conditions and prospects. They appraised Strasburg's business risk based on its past financial statements and its current technology and customer base. The bankers also forecasted financial statements with different capital structures and analyzed such key ratios as the current ratio and the times-interest-earned ratio. Finally, they factored in current conditions in the financial markets, including interest rates paid by firms in Strasburg's industry. Based on their analysis and judgment, they estimated interest rates at various capital structures as shown in Row 2 of Figure 15-5, starting with a 7.7% cost of debt.[31]

[31]For a description of a technique for estimating the cost of debt, see Jules H. Van Binsbergen, John H. Graham, and Jie Yang, "An Empirical Model of Optimal Capital Structure," *Journal of Applied Corporate Finance*, Vol. 23, No. 4, Fall, 2011, pp. 34–59. They also provide an approach for estimating the optimal capital structure that explicitly incorporates the tax benefits of debt net of the financial distress costs and other costs.

Source: See the file ***Ch15 Tool Kit.xlsx***. Numbers are reported as rounded values for clarity, but are calculated using *Excel*'s full precision. Thus, intermediate calculations using the figure's rounded values will be inexact.

Notes:

1. The percent financed with equity is $w_s = 1 - w_d$.
2. The interest rate on debt, r_d, is obtained from investment bankers. This is the resulting average rate on all debt, not the marginal rate on new debt.
3. Beta is estimated using Hamada's formula, the unlevered beta of 1.09, and a tax rate of 40%: $b = b_U[1 + (1 - T)(w_d / w_s)]$.
4. The cost of equity is estimated using the CAPM formula with a risk-free rate of 6.3% and a market risk premium of 6%: $r_s = r_{RF} + b(RP_M)$.
5. The after-tax cost of debt is $r_d(1 - T)$, where T = 40%.
6. The weighted average cost of capital is calculated as $WACC = w_d r_d(1 - T) + w_s r_s$.
7. The value of the firm's operations is calculated as $V_{op} = [FCF(1 + g_L)] / (WACC - g_L)$, where FCF = $30 million and $g_L = 0$.
8. Debt $= w_d \times V_{op}$.
9. The intrinsic value of equity after the recapitalization and repurchase is $S_{Post} = V_{op} - \text{Debt} = w_s \times V_{op}$.
10. The number of shares after the recap has been completed is found using this equation: $n_{Post} = n_{Prior} \times [(V_{opNew} - D_{New}) / (V_{opNew} - D_{Old})]$. The subscript "Old" indicates values from the original capital structure, where $w_d = 20\%$; the subscript "New" indicates values at the current capital structure after the recap and repurchase; and the subscript "Post" indicates values after the recap and repurchase.
11. The price after the recap and repurchase is $P_{Post} = S_{Post} / n_{Post}$, but we can also find the price as $P_{Post} = (V_{opNew} - D_{Old})n_{Prior}$.
12. EBIT is $50 million; see Figure 15-1. Net income is $NI = (EBIT - r_d D)(1 - T)$.
13. Earnings per share is $EPS = NI / n_{Post}$.

This rate increases to 16% if the firm finances 60% of its capital structure with debt. (*Note:* These are the average rates for all of Strasburg's possible debt levels, not the marginal rates for the next dollar of debt.) Strasburg's current situation is in Column D and is shown in blue. (We will explain all the rows in Figure 15-5 in the following discussion.)

ESTIMATING THE COST OF EQUITY (r_s) WITH THE HAMADA EQUATION

An increase in the debt ratio also increases the risk faced by shareholders, and this has an effect on the cost of equity, r_s. Recall from Chapter 6 that a stock's beta is the relevant measure of risk for diversified investors. Moreover, it has been demonstrated, both

theoretically and empirically, that beta increases with financial leverage. The **Hamada equation** specifies the effect of financial leverage on beta:[32]

$$b = b_U[1 + (1 - T)(D/S)] \quad \textbf{(15-11)}$$

Here D is the market value of the debt and S is the market value of the equity. The Hamada equation shows how increases in the market value debt/equity ratio increase beta. Here b_U is the firm's **unlevered beta** coefficient—that is, the beta it would have if it had no debt. In that case, beta would depend entirely on business risk and thus be a measure of the firm's "basic business risk."

Sometimes it is more convenient to work with the percentages of debt and equity at which the firm is financed (w_d and w_s) rather than the dollar values of D and S. Notice that w_d and w_s are defined as $D/(D + S)$ and $S/(D + S)$, respectively. This means that the ratio w_d/w_s is equal to the ratio D/S. Substituting these values gives us another form of Hamada's formula:

$$b = b_U[1 + (1 - T)(w_d/w_s)] \quad \textbf{(15-11a)}$$

Often we know the current capital structure and beta but wish to know the unlevered beta. We find this by rearranging Equation 15-11a as follows:

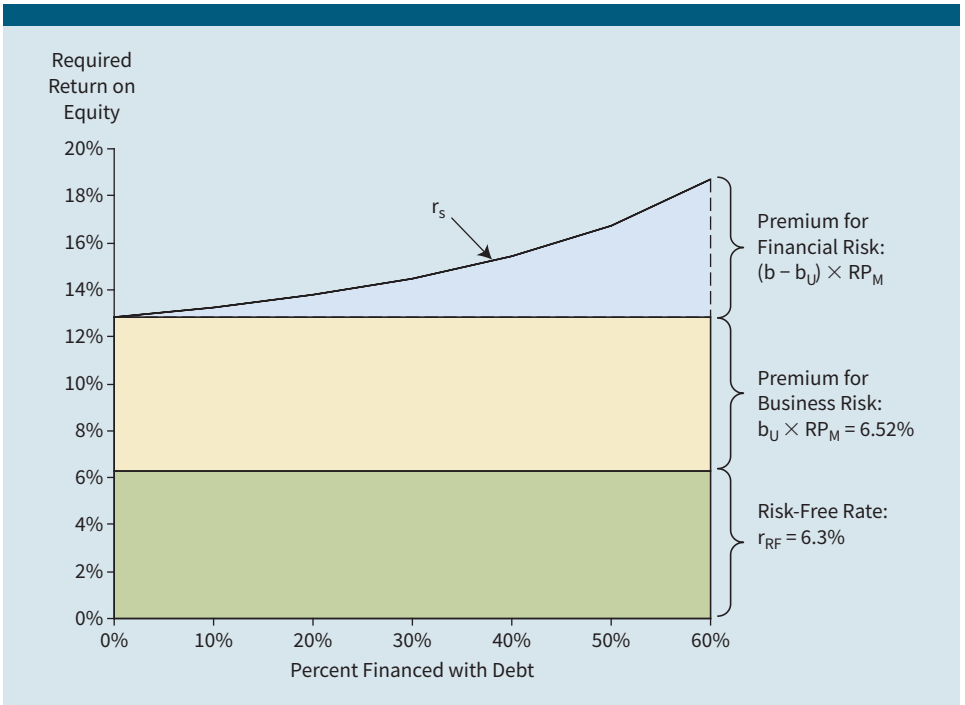
$$b_U = b/[1 + (1 - T)(w_d/w_s)] \quad \textbf{(15-12)}$$

For Strasburg, the unlevered beta is:

$$\begin{aligned} b_U &= 1.25/[1 + (1 - 0.40)(0.20/0.80)] \\ &= 1.087 \end{aligned}$$

Using this unlevered beta, we can then apply Hamada's formula in Equation 15-11a to determine estimates of Strasburg's beta for different capital structures. These results are reported in Line 3 of Figure 15-5.

Recall from Section 15-6a that the risk-free rate is 6.3% and the market risk premium is 6%. We can use the CAPM and the previously estimated betas to estimate Strasburg's cost of equity for different capital structures (which cause Strasburg's beta to change). These results are shown in Line 4 of Figure 15-5. As expected, Strasburg's cost of equity increases as its debt increases. Figure 15-6 graphs Strasburg's required return on equity at different debt ratios. Observe that the cost of equity consists of the 6.3% risk-free rate, a constant premium for business risk in the amount of $RP_M(b_U) = 6.522\%$, and a premium for financial risk in the amount of $RP_M(b - b_U)$ that starts at zero (because $b = b_U$ for zero debt) but rises at an increasing rate as the debt ratio increases.



THE WEIGHTED AVERAGE COST OF CAPITAL AT DIFFERENT LEVELS OF DEBT

Line 6 of Figure 15-5 shows Strasburg's weighted average cost of capital, WACC, at different capital structures. As the debt ratio increases, the costs of both debt and equity

[32]See Robert S. Hamada, "Portfolio Analysis, Market Equilibrium, and Corporation Finance," *Journal of Finance,* March 1969, pp. 13–31. For a comprehensive framework, see Robert A. Taggart, Jr., "Consistent Valuation and Cost of Capital Expressions with Corporate and Personal Taxes," *Financial Management,* Autumn 1991, pp. 8–20.

FIGURE 15-6
Strasburg's Required Rate of Return on Equity at Different Debt Levels

rise, at first slowly but then at an accelerating rate. Eventually, the increasing costs of these two components offset the fact that more debt (which is still less costly than equity) is being used. At 40% debt, Strasburg's WACC hits a minimum of 11.63%; Column F is shown in silver to indicate that it is the capital structure with the minimum WACC. Notice that the WACC begins to increase for capital structures with more than 40% debt. Figure 15-7 shows how the WACC changes as debt increases.

Also note that even though the component cost of equity is always higher than that of debt, only using debt would not maximize value. If Strasburg were to issue more than 40% debt, then the costs of both debt and equity would increase in such a way that the overall WACC would increase, because the cost of debt would increase by more than the cost of equity.

15-6c Estimating the Firm's Value

As we showed previously, Strasburg currently has a $250 million intrinsic value of operations: $w_d = 20\%$, WACC = 12%, FCF = $30 million, and zero growth in FCF. Using the same approach as in Section 15-6a, we can use the data in Figure 15-5 to estimate Strasburg's value of operations at different capital structures; these results are reported in Line 7 of Figure 15-5 and are graphed in Figure 15-8.[33] The maximum value of $257.86 million occurs at a capital structure with 40% debt, which also is the capital structure that minimizes the WACC.

[33]In this analysis we assume that Strasburg's expected EBIT and FCF are constant for the various capital structures. In a more refined analysis, we might try to estimate any possible declines in FCF at high levels of debt as the threat of bankruptcy becomes imminent.

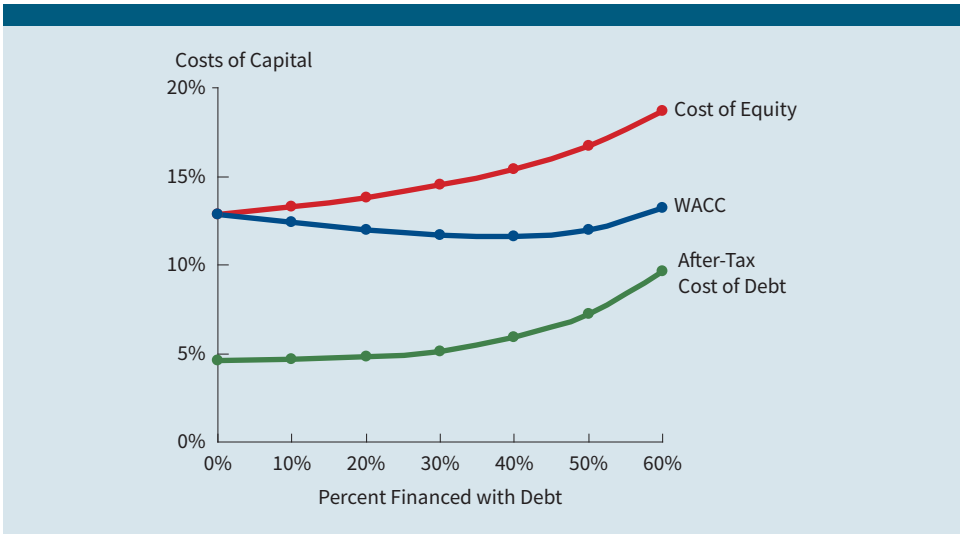
FIGURE 15-7
Effects of Capital Structure on the Cost of Capital



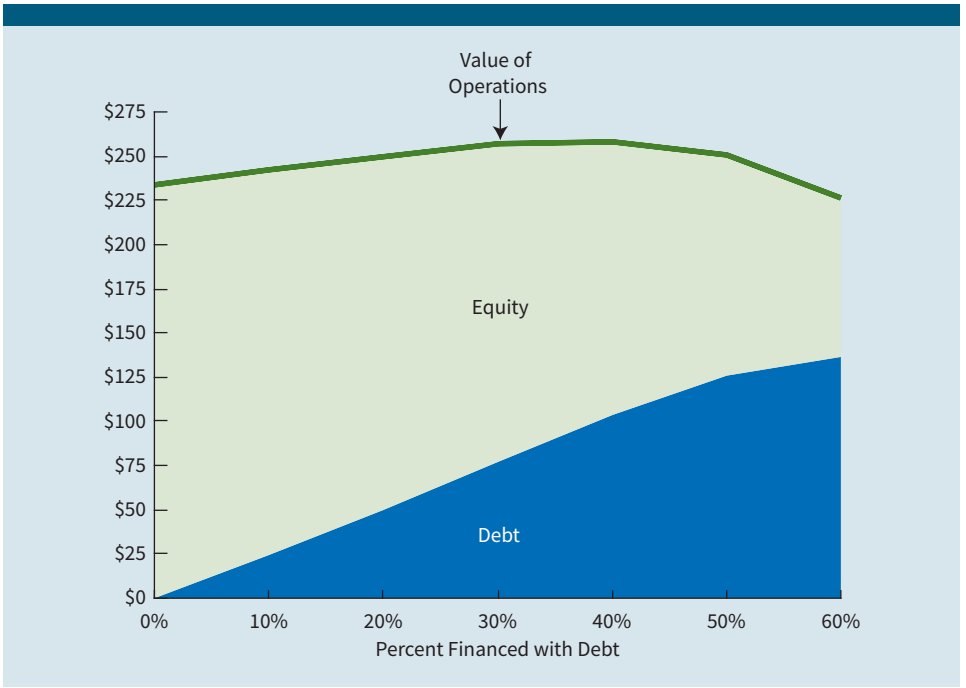


FIGURE 15-8
Effects of Capital Structure on the Value of Operations (Millions of Dollars)

Notice that the value of the firm initially increases but then begins to fall. As discussed earlier, the value initially rises because the WACC initially falls. But the rising costs of equity and debt eventually cause the WACC to increase, causing the value of the firm to fall. Notice how flat the curve is around the optimal level of debt. Thus, it doesn't make a great deal of difference whether Strasburg's capital structure has 30% debt or

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. 40% debt. Also, notice that the maximum value is about 10% greater than the value with no debt. Although this example is for a single company, the results are not unrealistic: The optimal capital structure for most firms can add 2% to 15% more value relative to zero debt, and there is a fairly wide range of w_d (from about 20% to 50%) over which value changes very little.

Figures 15-5 and 15-8 also show the values of debt and equity for each capital structure. The value of debt is found by multiplying the value of operations by the percentage of the firm that is financed by debt: Debt $= w_d \times V_{op}$. The intrinsic value of equity is found in a similar manner: $S = V_{op} - \text{Debt} = w_s \times V_{op}$. Even though the intrinsic value of equity falls as debt increases, the wealth of shareholders is maximized at the maximum value of operations, as we explain in the next section.

SELF-TEST

What happens to the costs of debt and equity when leverage increases? Explain.

Use the Hamada equation to calculate the unlevered beta for JAB Industries, assuming the following data: Levered beta = b = 1.4; T = 40%; w_d = 45%. **(0.939)**

Suppose r_{RF} = 6% and RP_M = 5%. What would be the cost of equity for JAB Industries if it had no debt? **(10.7%)** *If w_d were 45%?* **(13.0%)**

15-7 Anatomy of a Recapitalization

Strasburg should **recapitalize**, meaning that it should issue enough additional debt to optimize its capital structure, and then use the debt proceeds to repurchase stock. As shown in Figure 15-5, a capital structure with 40% debt is optimal. But before tackling the **recap**, as it is commonly called, let's consider the sequence of events, starting with the situation before Strasburg issues any additional debt. Figure 15-4 shows the valuation analysis of Strasburg at a capital structure consisting of 20% debt and 80% equity. These results are repeated in Column 1 of Figure 15-9, along with the shareholder wealth, which consists entirely of $200 million in stock before the repurchase. The next step is to examine the impact of Strasburg's debt issuance.

15-7a Strasburg Issues New Debt but Has Not Yet Repurchased Stock

The next step in the recap is to issue debt and announce the firm's intent to repurchase stock with the newly issued debt. At the optimal capital structure of 40% debt, the value of the firm's operations is $257.86 million, as calculated in Figure 15-5 and repeated in Column 2 of Figure 15-9. This value of operations is greater than the $250 million value of operations for $w_d = 20\%$ because the WACC is lower. Notice that Strasburg raised its debt from $50 million to $103.14 million, an increase of $53.14 million. Because Column 2 reports data prior to the repurchase, Strasburg has short-term investments in the amount of $53.14 million, the amount that was raised in the debt issuance but that has not yet been used to repurchase stock.[34] As Figure 15-9 shows, Strasburg's intrinsic value of equity is $207.86 million.

[34]These calculations are shown in the *Excel* file ***Ch15 Tool Kit.xlsx*** on the textbook's Web site. The values reported in the text are rounded, but the values used in calculations in the spreadsheet are not rounded.

Source: See the file ***Ch15 Tool Kit.xlsx.*** Numbers are reported as rounded values for clarity, but are calculated using *Excel*'s full precision. Thus, intermediate calculations using the figure's rounded values will be inexact.

Notes:

1. The value of ST investments in Column 2 is equal to the amount of cash raised by issuing additional debt. This cash has not yet been used to repurchase shares, so it is held in the form of short-term investments: ST investments $= D_{New} - D_{Old}$.
2. The value of ST investments in Column 3 is zero because the funds have been used to repurchase shares of stock.
3. The number of shares in Column 3 reflects the shares repurchased: $n_{Post} = n_{Prior} - (Cash_{Rep}/P_{Prior}) = n_{Prior} - [(D_{New} - D_{Old})/P_{Prior}]$.

Because Strasburg has not yet repurchased any stock, it still has 10 million shares outstanding. Therefore, the price per share after the debt issue but prior to the repurchase is:

$$\begin{aligned} P_{Prior} &= S_{Prior}/n_{Prior} \\ &= \$207.86/10 = \$20.79 \end{aligned}$$

Column 2 of Figure 15-9 summarizes these calculations and also shows the wealth of the shareholders. The shareholders own Strasburg's equity, which is worth $207.86 million. Strasburg has not yet made any cash distributions to shareholders, so the total wealth of shareholders is $207.86 million. The new wealth of $207.86 million is greater than the initial wealth of $200 million, so the recapitalization has added value to Strasburg's shareholders. This increase in value comes from reducing the amount of taxes Strasburg pays and represents a transfer of value from the government to Strasburg's shareholders. By increasing the level of debt, interest expense increases and taxes go down. Notice also that the recapitalization caused the intrinsic stock price to increase from $20.00 to $20.79.[35]

[35]The increase in value is, in principle, the present value of the new interest tax shields as in Equation 15-8. Hamada's formula for levering beta, Equation 15-11, was developed for the special case in which debt is risk free. Since $r_d > r_{Rf}$ in this example, the additional value doesn't exactly equal the present value of the tax shields. Chapter 21 develops an equation similar to Equation 15-11 that deals with risky debt, and when it is used to lever and unlever beta, the additional value from a recapitalization is precisely equal to the present value of the new interest tax shields.

Summarizing these results, we see that the issuance of debt and the resulting change in the optimal capital structure caused: (1) the WACC to decrease, (2) the value of operations to increase, (3) shareholder wealth to increase, and (4) the stock price to increase.

15-7b Strasburg Repurchases Stock

What happens to the stock price during the repurchase? In Chapter 14, we discussed repurchases and showed that a repurchase does not change the stock price. It is true that the additional debt will change the WACC and the stock price prior to the repurchase (P_{Prior}), but the subsequent repurchase itself will not affect the post-repurchase stock price (P_{Post}).[36] Therefore, $P_{Post} = P_{Prior}$. (Keep in mind that P_{Prior} is the price immediately prior to the repurchase, not the price prior to announcing the recapitalization and issuing the debt.)

Strasburg uses the entire amount of cash raised by the debt issue to repurchase stock. The total cash raised is equal to $D_{New} - D_{Old}$. The number of shares repurchased is equal to the cash raised by issuing debt divided by the repurchase price:

$$\text{Number of shares repurchased} = \frac{D_{New} - D_{Old}}{P_{Prior}} \quad \textbf{(15-13)}$$

Strasburg repurchases $(\$103.14 - \$50)/\$20.79 = 2.56$ million shares of stock.

The number of remaining shares after the repurchase, n_{Post}, is equal to the initial number of shares minus the number that is repurchased:

$$\begin{aligned} n_{Post} &= \text{Number of outstanding shares remaining after the repurchase} \\ &= n_{Prior} - \text{Number of shares repurchased} \\ &= n_{Prior} - \frac{D_{New} - D_{Old}}{P_{Prior}} \end{aligned} \quad \textbf{(15-14)}$$

For Strasburg, the number of remaining shares after the repurchase is:

$$\begin{aligned} n_{Post} &= n_{Prior} - (D_{New} - D_{Old})/P_{Prior} \\ &= 10 - (\$103.14 - \$50)/\$20.79 \\ &= 7.44 \text{ million} \end{aligned}$$

Column 3 of Figure 15-9 summarizes these post-repurchase results. The repurchase doesn't change the value of operations, which remains at $257.86 million. However, the short-term investments are sold and the cash is used to repurchase stock. Strasburg is left with no short-term investments, so the intrinsic value of equity is:

$$S_{Post} = \$257.86 - \$103.14 = \$154.72 \text{ million}$$

[36] As we discuss in Chapter 14, a stock repurchase may be a signal of a company's future prospects or it may be the way a company "announces" a change in capital structure, and either of these situations could have an impact on estimated free cash flows or WACC. However, neither situation applies to Strasburg.

After the repurchase, Strasburg has 7.44 million shares of stock. We can verify that the intrinsic stock price has not changed:[37]

$$P_{Post} = S_{Post}/n_{Post} = \$154.72/7.44 = \$20.79$$

Shareholders now own an equity position in the company worth only $154.72 million, but they have received a cash distribution in the amount of $53.14 million, so their total wealth is equal to the value of their equity plus the amount of cash they received: $154.72 + $53.14 = $207.86.

Here are some points worth noting. As shown in Column 3 of Figure 15-9, the change in capital structure clearly added wealth to the shareholders, increased the price per share, and increased the cash (in the form of short-term investments) temporarily held by the company. However, the repurchase itself did not affect shareholder wealth or the price per share. The repurchase did reduce the cash held by the company and the number of shares outstanding, but shareholder wealth stayed constant. After the repurchase, shareholders directly own the funds used in the repurchase; before the repurchase, shareholders indirectly own the funds. In either case, shareholders own the funds. The repurchase simply takes them out of the company's account and puts them into the shareholders' personal accounts.

The approach we've described here is based on the corporate valuation model, and it will always provide the correct values for S_{Post}, n_{Post}, and P_{Post}. However, there is a quicker way to calculate these values if the firm has no short-term investments either before or after the recap (other than the temporary short-term investments held between the time debt was issued and shares repurchased). After the recap is completed, the percentage of equity in the capital structure, based on market values, is equal to $1 - w_d$ if the firm holds no other short-term investments. Therefore, the value of equity after the repurchase is:

$$S_{Post} = V_{opNew}(1 - w_d) \quad \textbf{(15-15)}$$

where we use the subscript "New" to indicate the value of operations at the new capital structure and the subscript "Post" to indicate the post-repurchase intrinsic value of equity.

The post-repurchase number of shares can be found using this equation:

$$n_{Post} = n_{Prior}\left[\frac{V_{opNew} - D_{New}}{V_{opNew} - D_{Old}}\right] \quad \textbf{(15-16)}$$

Given the value of equity and the number of shares, it is straightforward to calculate the intrinsic price per share as $P_{Post} = S_{Post}/n_{Post}$. But we can also calculate the post-repurchase price using:

$$P_{Post} = \frac{V_{opNew} - D_{Old}}{n_{Prior}} \quad \textbf{(15-17)}$$

[37]There may be a small rounding difference due to using rounded numbers in intermediate steps. See the *Excel* file ***Ch15 Tool Kit.xlsx*** for the exact calculations.

FIGURE 15-10
Effects of Capital Structure on Stock Price and Earnings per Share

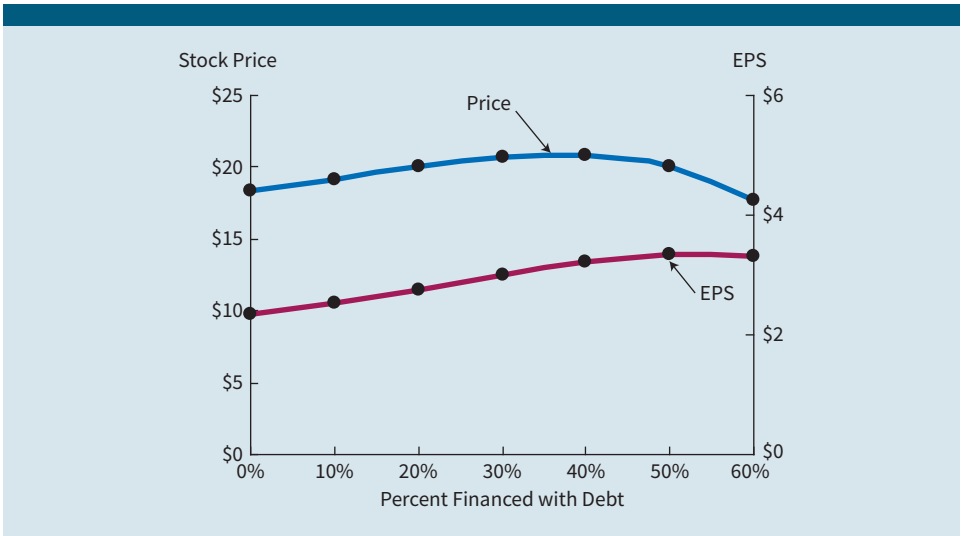

Figure 15-5 reports the number of shares and the intrinsic price per share in Lines 10–11. Notice that the number of shares goes down as debt goes up because the debt proceeds are used to buy back stock. Notice also that the capital structure that maximizes stock price, $w_d = 40\%$, is the same capital structure that optimizes the WACC and the value of operations.

Figure 15-5 also reports the earnings per share for the different levels of debt. Figure 15-10 graphs the intrinsic price per share and the earnings per share. Notice that the maximum earnings per share is at 50% debt even though the optimal capital structure is at 40% debt. This means that maximizing EPS will not maximize shareholder wealth.

15-7c Recapitalization: A Post-Mortem

In Chapter 12, we saw how a company can increase its value by improving its operations. There is good news and bad news regarding this connection. The good news is that small improvements in operations can lead to huge increases in value. The bad news is that it's often difficult to improve operations, especially if the company is already well managed and is in a competitive industry.

If instead you seek to increase a firm's value by changing its capital structure, we again have good news and bad news. The good news is that changing capital structure is easy—just call an investment banker and issue debt (or issue equity if the firm has too much debt). The bad news is that this will add only a relatively small amount of value. Of course, any additional value is better than none, so it's hard to understand why there are some mature firms with zero debt.

Finally, some firms have more debt than is optimal and should recapitalize to a lower debt level. This is called *deleveraging*. We can use exactly the same approach and the same formulas as we used for Strasburg. The difference is that the debt will go down and the number of shares will go up. In other words, the company will issue new shares of stock and then use the proceeds to pay off debt, resulting in a capital structure with less debt and lower interest payments.

Deleveraging

Many households, nonfinancial businesses, and financial institutions loaded up on easy credit during the run-up to the global economic crisis and found themselves with too much debt during the recession that began in 2007. The process of reducing debt is called *deleveraging,* and it is painful for individuals and the economy.

The debt-to-income ratio for households increased from around 80%–90% during the 1990s to a peak of 133% in 2007. To deleverage, many households cut spending on consumer goods and paid off some of their debt. This belt-tightening is difficult for the individual households, but it also is difficult for the economy because decreased spending leads to economic contraction and job losses. Other households deleveraged by declaring bankruptcy, with over 1.5 million people filing in 2010.

Like individuals, businesses can deleverage by paying off debt or by declaring bankruptcy, and many did so during this global economic crisis. But businesses can also deleverage by issuing equity. For example, Dunkin' Brands Group, owner of the Dunkin' Donuts and Baskin-Robbins brands, issued $427 million in stock in July 2011, part of which was used to pay down debt. And Wells Fargo and Morgan Stanley issued over $12 billion in stock in May 2009. A problem with deleveraging via stock issuances is that the stock price usually has been beaten down so much by the time of deleveraging that the new investors get a larger stake in the company, which dilutes the existing stockholders. But the bottom line is that dilution is better than bankruptcy!

SELF-TEST

A firm's value of operations is equal to $800 million after a recapitalization. (The firm had no debt before the recap.) The firm raised $200 million in new debt and used this to buy back stock. The firm had no short-term investments before or after the recap. After the recap, $w_d = 25\%$. *The firm had 10 million shares before the recap. What is S (the value of equity after the recap)?* **($600 million)** *What is* P_{Post} *(the stock price after the recap)?* **($80/share)** *What is* n_{Post} *(the number of remaining shares after the recap)?* **(7.5 million)**

15-8 Risky Debt and Equity as an Option

In the previous sections, we evaluated equity and debt using the standard discounted cash flow techniques. However, we saw in Chapter 11 that if there is an opportunity for management to make a change as a result of new information after a project or investment has been started, then there might be an option component to the project or investment being evaluated. This type of opportunity also applies to managers of levered firms.

For example, consider Kunkel Inc., a small manufacturer of electronic wiring harnesses and instrumentation located in Minot, North Dakota. Kunkel has just issued some zero coupon bonds which mature in 5 years and have a $10 million face value. Kunkel plans to invest the debt proceeds in several new projects. What decision will management make when the debt comes due? The answer depends on how much the firm is worth in 5 years.

Suppose the company is worth a total of $22 million in 5 years. In this case, it will pay off the $10 million loan, either by liquidating assets or refinancing the debt. Either way, the stockholders' net value is $12 million:

$$\begin{aligned}\text{Value of equity} &= \text{Total value} - \text{Face value due on debt}\\ &= \$22 - \$10 = \$12 \text{ million}\end{aligned}$$

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Now suppose that business has gone poorly and the firm is worth only $9 million in 5 years. In that case, the firm is economically bankrupt, because its value is less than the amount of debt due. Management will choose to default on the loan and turn the company over to the debtholders, who will either keep the company or sell it. Either way, the original stockholders' value will be zero.

Notice that the stockholders' value in 5 years resembles a call option with a strike price equal to the loan amount—the stockholders get zero if the company is worth less than the loan's face value but they get the excess if the company is worth more than the face value. We can apply the same option pricing techniques from Chapter 8 to estimate the value of equity and to provide insights into managerial risk incentives.

15-8a Using the Black-Scholes Option Pricing Model to Value Equity

Recall from Chapter 8 that the value of a call option depends on five factors: the price of the underlying asset, the strike price (X), the risk-free rate (r_{RF}), the time to expiration (T), and the volatility of the market value of the underlying asset (σ). When applied to a levered firm, the underlying asset is the total value of the firm (denoted here by P instead of V_L to show how it is used in the Black-Scholes model). The strike price is the face value of the debt and the expiration date is the bond's maturity date.

resource

*See **Ch15 Tool Kit.xlsx** on the textbook's Web site for all calculations.*

The total value of the firm at the time it issues the debt but before it has yet invested the proceeds is the value of operations (which reflects expected future free cash flows of existing assets and growth plans) plus the proceeds from issuing debt. For Kunkel, the total value is $20 million when the debt is issued, the volatility is 40%, and the risk-free rate is 6%. The inputs for the Black-Scholes model are as follows:

$$\begin{aligned} P &= \$20 \text{ million} \\ X &= \$10 \text{ million} \\ t &= 5 \text{ years} \\ r_{RF} &= 6\% \\ \sigma &= 40\% \end{aligned}$$

The value of a European call option, as shown in Chapter 8, is:

$$V_0 = P[N(d_1)] - Xe^{-r_{RF}t}[N(d_2)] \quad \textbf{(15-18)}$$

where

$$d_1 = \frac{\ln(P/X) + (r_{RF} + \sigma^2/2)t}{\sigma\sqrt{t}} \text{ and } d_2 = d_1 - \sigma\sqrt{t} \quad \textbf{(15-19)}$$

Using the inputs for Kunkel, the values of d_1 and d_2 are:

$$d_1 = \frac{\ln(20/10) + (0.06 + 0.40^2/2)5}{0.40\sqrt{5}} = 1.5576$$

$$d_2 = 1.5576 - 0.40\sqrt{5} = 0.6632$$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Using the *Excel* **NORMSDIST** function gives $N(d_1) = N(1.5576) = 0.9403$, $N(d_2) = N(0.6632) = 0.7464$. Using Equation 15-18, the Black-Scholes value is:

$$V = \$20(0.9403) - \$10e^{-0.06(5)}(0.7464) = \$13.28 \text{ million}$$

This means that the value of Kunkel's equity at the time it issues debt is $13.28 million. Because the values of debt and equity must sum to the total value of $20 million, the value of Kunkel's debt (at the issue date) is:

$$\begin{aligned}\text{Debt value} &= \text{Total value} - \text{Equity value}\\ &= \$20 - \$13.28 = \$6.72 \text{ million}\end{aligned}$$

Recall from Chapter 4 that we can determine the rate (I) on a single future value (FV) at Year N if we know the present value (PV):

$$I = [(FV/PV)^{(1/N)}] - 1 \quad \textbf{(15-20)}$$

The rate on the zero coupon bond is its yield to maturity, so we can apply Equation 15-20 to determine the yield on the bond at the time it is issued:

$$\text{Yield on debt} = [(\$10/\$6.72)^{(1/5)}] - 1 = 0.0827 = 8.27\%$$

Thus, when Kunkel issues the debt, it receives $6.72 million and the yield on the debt is 8.27%. Notice that the yield on the debt, 8.27%, is greater than the 6% risk-free rate because the debt has default risk. In particular, the debtholders expect Kunkel to invest in projects with a total volatility of 40%, which means it is possible that the company will be worth less than $10 million when the debt matures.

15-8b Managerial Risk Incentives

The debt's yield depends on debtholders' perception of Kunkel's risk, which is determined in part by what debtholders expect management to do with the $6.72 million debt proceeds. Suppose Kunkel's management can find a way to increase future free cash flow volatility without reducing the value of operations (i.e., invest in projects that maintain NPV but that have higher risk). This will not change the total value of the firm, but it will change the relative values of debt and equity because the value of equity is like a call option on the firm's value (recall from Chapter 8 that options are worth more when volatility is higher). Table 15-2 shows different levels of volatility that correspond to management's choice of projects. For each volatility level, the table reports the total value, the value of equity, and the value of debt.

Notice in Table 15-2 that the total value remains constant because management is accepting projects with identical NPVs even though they have different risk levels. The row for 40% volatility (shown in blue) reports the values expected by the lenders *before* the debt is issued. However, suppose management instead undertakes projects that increase its risk from a volatility of 40% to a volatility of 80% *after* the debt is issued. This will cause Kunkel's equity to increase in value by $2.53 million to $15.81 million, which is a 19% gain. Notice that the value of debt will decrease by the same dollar amount. Therefore, increasing risk causes a transfer of wealth from bondholders to stockholders. The reverse occurs if Kunkel undertakes projects that are safer than originally planned.

Investing borrowed funds in riskier assets than anticipated by lenders is called **bait and switch** because the firm obtains the money by promising one investment policy and then switches to another policy. The bait-and-switch problem is more severe when

TABLE 15-2
The Value of Kunkel's Debt and Equity for Various Levels of Volatility (Millions of Dollars)

Standard Deviation of Total Value	Total Value	Value of Equity	Value of Debt
20%	$20	$12.62	$7.38
40	20	14.51	5.49
60	20	16.96	3.04
80	20	13.28	6.72
100	20	15.81	4.19

Source: Numbers in the table are shown as rounded values for clarity in reporting. However, unrounded values are used for all calculations. See the *Excel* ***Tool Kit*** for this chapter.

a firm's value is low relative to its level of debt. For example, suppose total value immediately falls to $11 million due to an unexpected change in the business environment. If the volatility remains at 40%, the value of equity drops to $5.25 million and the value of debt drops to $5.75 million (see the ***Tool Kit*** for all calculations). If management now doubles volatility, the equity value increases to $7.69 million, an increase of 46%, coming at the expense of debtholders.[38] Therefore, the incentive for management to "roll the dice" with borrowed funds can be enormous—if management owns many stock options, then their payoff from rolling the dice is even greater than the payoff to stockholders!

Bondholders are aware of these incentives and write covenants into debt issues that restrict management's ability to invest in riskier projects than originally promised. However, their attempts to protect themselves are not always successful, as the failures of Enron, Lehman Brothers, and AIG demonstrate. The combination of a risky industry, high levels of debt, and option-based compensation has proven to be very dangerous.

SELF-TEST

Discuss how equity can be viewed as an option. Who has the option and what decision can they make?

Why would management want to increase the riskiness of the firm? Why would this make bondholders unhappy?

What can bondholders do to limit management's ability to bait and switch?

15-9 Managing the Maturity Structure of Debt

In conjunction with choosing how much debt to have in its capital structure, firms must choose the maturities of the various securities that make up its debt. The following sections explain the factors associated with the choice of maturity structure.

[38]For extremely high volatilities, the yield on the debt is much higher than any reasonable required return on stock; see the ***Tool Kit*** for calculations. When debt is supposedly safer than equity, why would its yield be so high? The answer is that although debtholders are indeed paid before stockholders, they don't get to participate in the very high payouts stockholders receive when the company does extremely well—debtholders only get the face value of the debt in those cases. But when the company does poorly, the debtholders only get to take over a poorly performing company. As the volatility increases, the probability of receiving ownership of a poorly performing company instead of the face value of debt increases, driving down the value of the debt. In the limit, as the volatility continues to increase, the value of the debt is driven to zero. Thus, the debt is actually much riskier than the stock when volatility is high!

15-9a Maturity Matching

Assume that Consolidated Tools, a Cincinnati machine tool manufacturer, made the decision to float a $25 million nonconvertible bond issue to help finance its 2016 capital budget. It must choose a maturity for the issue, taking into consideration the shape of the yield curve, management's own expectations about future interest rates, and the maturity of the assets being financed. To illustrate how asset maturities affect the choice of debt maturities, suppose Consolidated's capital projects consist primarily of new milling machinery. This machinery has an expected economic life of 10 years (even though it falls into the MACRS 5-year class life). Should Consolidated use debt with a 5-year, 10-year, 20-year, 30-year, or some other maturity?

Note that some of the new capital will come from common equity, which is permanent capital. On the other hand, debt maturities can be specified at the time of issue. If Consolidated financed its capital budget with 10-year sinking fund bonds, it would be matching asset and liability maturities. The cash flows resulting from the new machinery could be used to make the interest and sinking fund payments on the issue, so the bonds would be retired as the machinery wore out.

If Consolidated used 1-year debt, then it would have to pay off this debt with cash flows derived from assets other than the machinery in question. Of course, the 1-year debt could probably be rolled over year after year, out to the 10-year asset maturity. However, if interest rates rose, then Consolidated would have to pay a higher rate when it rolled over its debt, and if the company experienced difficulties, then it might not be able to refund the debt at a reasonable rate. Conversely, if it used 20-year or 30-year debt, it would have to service the debt long after the assets that were purchased with the funds had been scrapped and had ceased providing cash flows. This would worry lenders.

For all these reasons, *the safest all-around financing strategy is to match debt maturities with asset maturities*. In recognition of this fact, firms generally place great emphasis on maturity matching, and this factor often dominates the debt maturity decision.

15-9b Effects of Interest Rate Levels and Forecasts

Financial managers also consider interest rate levels and forecasts, both absolute and relative, when making financing decisions. For example, if long-term interest rates are high by historical standards and are expected to fall, managers will be reluctant to issue long-term debt, which would lock in those costs for long periods. We already know that one solution to this problem is to use a call provision, because callability permits refunding should interest rates drop. This flexibility comes at a cost, however, because of the call premium and also because the firm must set a higher coupon on callable debt. Floating-rate debt could be used, but another alternative would be to finance with short-term debt whenever long-term rates are historically high, and then, assuming that interest rates subsequently fall, sell a long-term issue to replace the short-term debt. Of course, this strategy has its risks: If interest rates move even higher, the firm will be forced to renew its short-term debt at higher and higher rates or to replace the short-term debt with a long-term bond that costs even more than it would have when the original decision was made.

15-9c Information Asymmetries

Consider two types of firms that need to raise funds to finance projects but that have high degrees of asymmetric information. The first type of fund has better prospects than investors expect and the second has worse prospects. How does the information asymmetry affect maturity choice?

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

In the first situation, managers may be reluctant to issue common stock because this might be taken as a negative signal. But if they issue debt, the interest rate will be too high because it reflects investors' expectations (which are too pessimistic compared to the better informed expectations of management). Rather than locking in a high rate for a long period, the firm can issue short-term debt. It also will have a too-high interest rate, but it can be refinanced at a lower rate when it comes due and the firm's excellent prospects have been realized.

In the second situation, a company with poorer prospects than expected by the market would wish to issue stock but would also be worried about the negative signal (which is justified in this case). It would prefer to lock in a better interest rate than its true situation warrants, so it would want to issue long-term debt.[39]

15-9d Amount of Financing Required

Obviously, the amount of financing required will influence the financing decision. This is mainly because of flotation costs. A $5 million debt financing, which is small in Wall Street terms, would most likely be done with a term loan or a privately placed bond issue, whereas a firm seeking $2 billion of new debt would most likely use a public offering of long-term bonds.

15-9e Availability of Collateral

Generally, secured debt is less costly than unsecured debt. Thus, firms with large amounts of marketable fixed assets are likely to use a relatively large amount of long-term debt, especially mortgage bonds. Additionally, each year's financing decision would be influenced by the amount of qualified assets available as security for new bonds.

15-9f Evidence on Debt Maturity in Practice

Professors Custódio, Ferreira, and Laureano show that the ratio of total debt to total assets (based on book values) has remained relatively stable at about 27% for the past 40 years for publicly traded companies.[40] However, the mix of long-term debt and short-term debt has changed dramatically. Long-term debt (maturing in more than 5 years) comprised about 62% of all debt financing in 1976, but has dropped to about 40% in recent years. In addition, the average original maturity of publicly issued debt has dropped from over 25 years to 11 years in that same period. What has caused this shift?

Part of the explanation is due to the changing nature of public companies. Before 1990, most IPOs were for relatively mature companies with a strong record of earnings. Since then, many smaller and riskier companies have gone public. Just as fewer of these companies pay dividends (as described in Chapter 14), fewer issue long-term debt. In fact, the maturity mix of debt issued by older companies has not changed significantly.

In general, many public companies today (mature and new) have high levels of informational asymmetry because they compete in complex product environments, including information technology, bio-technology, and pharmaceuticals. Theory suggests that such firms should raise capital from debt rather than equity and should raise short-term debt rather than long-term debt, and this is what the evidence shows.

---

[39]If the market expects firms in these two situations to behave as described, then it will interpret the choice of short-term debt versus long-term debt as a signal regarding the quality of the issuer. See M. Flannery, "Asymmetric Information and Risky Debt Maturity Choice," *Journal of Financial Economics,* Vol. 41, 1986, pp. 19–37.

[40]For more details, see C. Custódio, M. Ferreira, and L. Laureano, "Why Are US Firms Using More Short-Term Debt?" *Journal of Financial Economics,* Vol. 108, 2013, pp. 182–212.

SELF-TEST

What are some factors that financial managers consider when choosing the maturity structure of their debt?

How do information asymmetries affect financing decisions?

SUMMARY

This chapter examined the effects of financial leverage on stock prices, earnings per share, and the cost of capital. The key concepts covered are listed here.

- A firm's **optimal capital structure** is the mix of debt and equity that maximizes the stock price. At any point in time, management has a specific **target capital structure** in mind, presumably the optimal one, but this target may change over time.
- **Business risk** is the risk inherent in the firm's operations if it uses no debt. A firm will have little business risk if the demand for its products is stable, if the prices of its inputs and products remain relatively constant, if it can adjust its prices freely if costs increase, and if a high percentage of its costs are variable and hence will decrease if sales decrease. Other things the same, the lower a firm's business risk, the higher its optimal debt ratio.
- **Financial leverage** is the extent to which fixed-income securities (debt and preferred stock) are used in a firm's capital structure. **Financial risk** is the added risk borne by stockholders as a result of financial leverage.
- **Operating leverage** is the extent to which fixed costs are used in a firm's operations. In business terminology, a high degree of operating leverage, other factors held constant, implies that a relatively small change in sales results in a large change in ROIC. ***Web Extension 15A*** describes additional measures of operating and financial leverage.
- If there are no corporate or personal taxes, Modigliani and Miller showed that the value of a levered firm is equal to the value of an otherwise identical but unlevered firm:

$$V_L = V_U$$

- If there are only corporate taxes, Modigliani and Miller showed that a firm's value increases as it adds debt due to the interest rate deductibility of debt:

$$V_L = V_U + TD$$

- If there are personal and corporate taxes, Miller showed that:

$$V_L = V_U + \left[1 - \frac{(1 - T_c)(1 - T_s)}{(1 - T_d)}\right]D$$

- The **Hamada equation** shows the effect of financial leverage on beta as follows:

$$b = b_U[1 + (1 - T)(D/S)]$$

- Firms can use their current beta, tax rate, and debt/equity ratio to derive their **unlevered beta, b_U**, as follows:

$$b_U = b/[1 + (1 - T)(D/S) = b/[1 + (1 - T)(w_d/w_s)]$$

- The **trade-off theory** of capital structure states that debt initially adds value because interest is tax deductible but that debt also brings costs associated with actual or

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

potential bankruptcy. The optimal capital structure strikes a balance between the tax benefits of debt and the costs associated with bankruptcy.

- **Signaling theory** assumes that there is **asymmetric information** because managers have more complete information than investors. A stock issue is viewed as a negative signal, whereas a bond issue is a neutral (or small negative) signal. As a result, companies try to avoid having to issue stock by maintaining a **reserve borrowing capacity**, and this means using less debt in "normal" times than the trade-off theory would suggest.
- A firm's owners may decide to use a relatively large amount of debt to constrain the managers. A *high debt ratio raises the threat of bankruptcy,* which not only carries a cost but also forces managers to be more careful and less wasteful with shareholders' money. Many of the corporate takeovers and leveraged buyouts in recent years were designed to improve efficiency by reducing the cash flow available to managers.
- When debt is risky, management may choose to default. If the debt is zero coupon debt, then this makes equity like an option on the value of the firm with a strike price equal to the face value of the debt.
- When a firm has risky debt and equity is like an option, management has an incentive to increase the firm's risk in order to increase the equity value at the expense of the debt value. This is called **bait and switch**.
- ***Web Extension 15B*** provides proofs of the MM propositions.

QUESTIONS

(15-1) Define each of the following terms:

a. Capital structure; business risk; financial risk
b. Operating leverage; financial leverage; break-even point
c. Reserve borrowing capacity

(15-2) What term refers to the uncertainty inherent in projections of future ROIC?

(15-3) Firms with relatively high nonfinancial fixed costs are said to have a high degree of what?

(15-4) "One type of leverage affects both EBIT and EPS. The other type affects only EPS." Explain this statement.

(15-5) Why is the following statement true? "Other things being the same, firms with relatively stable sales are able to carry relatively high debt ratios."

(15-6) Why do public utility companies usually have capital structures that are different from those of retail firms?

(15-7) Why is EBIT generally considered to be independent of financial leverage? Why might EBIT be influenced by financial leverage at high debt levels?

(15-8) If a firm went from zero debt to successively higher levels of debt, why would you expect its stock price to first rise, then hit a peak, and then begin to decline?

(15-9) Your firm's CEO has just learned about options and how your firm's equity can be viewed as an option. Why might he want to increase the riskiness of the firm, and why might the bondholders be unhappy about this?

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). SELF-TEST PROBLEMS

Solutions Shown in Appendix A

(ST-1) Optimal Capital Structure

The Rogers Company is currently in this situation: (1) EBIT = $4.7 million; (2) tax rate, T = 40%; (3) value of debt, D = $2 million; (4) r_d = 10%; (5) r_s = 15%; (6) shares of stock outstanding, n = 600,000; and (7) stock price, P = $30. The firm's market is stable and it expects no growth, so all earnings are paid out as dividends. The debt consists of perpetual bonds.

a. What is the total market value of the firm's stock, S, and the firm's total market value, V?
b. What is the firm's weighted average cost of capital?
c. Suppose the firm can increase its debt by issuing debt and repurchasing stock so that its capital structure will have 50% debt, based on market values. At this level of debt, its cost of equity rises to 18.5% and its interest rate on all debt will rise to 12%. (It will have to call and refund the old debt.) What is the WACC under this capital structure? What is the total value? How much debt will it issue, and what is the stock price after the repurchase? How many shares will remain outstanding after the repurchase?

(ST-2) Hamada Equation

Lighter Industrial Corporation (LIC) is considering a large-scale recapitalization. Currently, LIC is financed with 25% debt and 75% equity. LIC is considering increasing its level of debt until it is financed with 60% debt and 40% equity. The beta on its common stock at the current level of debt is 1.5, the risk-free rate is 6%, the market risk premium is 4%, and LIC faces a 40% federal-plus-state tax rate.

a. What is LIC's current cost of equity?
b. What is LIC's unlevered beta?
c. What will be the new beta and new cost of equity if LIC recapitalizes?

PROBLEMS

Answers Are in Appendix B

EASY PROBLEMS 1–6

(15-1) Break-Even Quantity

Shapland Inc. has fixed operating costs of $500,000 and variable costs of $50 per unit. If it sells the product for $75 per unit, what is the break-even quantity?

(15-2) Unlevered Beta

Counts Accounting's beta is 1.15 and its tax rate is 40%. If it is financed with 20% debt, what is its unlevered beta?

(15-3) Premium for Financial Risk

Ethier Enterprise has an unlevered beta of 1.0. Ethier is financed with 50% debt and has a levered beta of 1.6. If the risk-free rate is 5.5% and the market risk premium is 6%, how much is the additional premium that Ethier's shareholders require to be compensated for financial risk?

(15-4) Value of Equity after Recapitalization

Nichols Corporation's value of operations is equal to $500 million after a recapitalization (the firm had no debt before the recap). It raised $200 million in new debt and used this to buy back stock. Nichols had no short-term investments before or after the recap. After the recap, w_d = 40%. What is S (the value of equity after the recap)?

(15-5) Stock Price after Recapitalization

Lee Manufacturing's value of operations is equal to $900 million after a recapitalization. (The firm had no debt before the recap.) Lee raised $300 million in new debt and used this to buy back stock. Lee had no short-term investments before or after the recap. After the recap, $w_d = 1/3$. The firm had 30 million shares before the recap. What is P (the stock price after the recap)?

(15-6) Shares Remaining after Recapitalization

Dye Trucking raised $150 million in new debt and used this to buy back stock. After the recap, Dye's stock price is $7.50. If Dye had 60 million shares of stock before the recap, how many shares does it have after the recap?

INTERMEDIATE PROBLEMS 7–8

(15-7) Break-Even Point

Schweser Satellites Inc. produces satellite earth stations that sell for $100,000 each. The firm's fixed costs, F, are $2 million, 50 earth stations are produced and sold each year, profits total $500,000, and the firm's assets (all equity financed) are $5 million. The firm estimates that it can change its production process, adding $4 million to assets and $500,000 to fixed operating costs. This change will reduce variable costs per unit by $10,000 and increase output by 20 units. However, the sales price on all units must be lowered to $95,000 to permit sales of the additional output. The firm has tax loss carryforwards that render its tax rate zero, its cost of equity is 16%, and it uses no debt.

a. What is the incremental profit? To get a rough idea of the project's profitability, what is the project's expected rate of return for the next year (defined as the incremental profit divided by the investment)? Should the firm make the investment? Why or why not?
b. Would the firm's break-even point increase or decrease if it made the change?
c. Would the new situation expose the firm to more or less business risk than the old one?

(15-8) Capital Structure Analysis

The Rivoli Company has no debt outstanding, and its financial position is given by the following data:

Assets (Market value = Book value)	$3,000,000
EBIT	$ 500,000
Cost of equity, r_s	10%
Stock price, P_0	$ 15
Shares outstanding, n_0	200,000
Tax rate, T (federal-plus-state)	40%

The firm is considering selling bonds and simultaneously repurchasing some of its stock. If it moves to a capital structure with 30% debt based on market values, its cost of equity, r_s, will increase to 11% to reflect the increased risk. Bonds can be sold at a cost, r_d, of 7%. Rivoli is a no-growth firm. Hence, all its earnings are paid out as dividends. Earnings are expected to be constant over time.

a. What effect would this use of leverage have on the value of the firm?
b. What would be the price of Rivoli's stock?
c. What happens to the firm's earnings per share after the recapitalization?
d. The $500,000 EBIT given previously is actually the expected value from the following probability distribution:

Probability	EBIT
0.10	($ 100,000)
0.20	200,000
0.40	500,000
0.20	800,000
0.10	1,100,000

Determine the times-interest-earned ratio for each probability. What is the probability of not covering the interest payment at the 30% debt level?

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

CHALLENGING PROBLEMS 9–12

(15-9) Capital Structure Analysis

Pettit Printing Company has a total market value of $100 million, consisting of 1 million shares selling for $50 per share and $50 million of 10% perpetual bonds now selling at par. The company's EBIT is $13.24 million, and its tax rate is 15%. Pettit can change its capital structure by either increasing its debt to 70% (based on market values) or decreasing it to 30%. If it decides to *increase* its use of leverage, it must call its old bonds and issue new ones with a 12% coupon. If it decides to *decrease* its leverage, it will call its old bonds and replace them with new 8% coupon bonds. The company will sell or repurchase stock at the new equilibrium price to complete the capital structure change.

The firm pays out all earnings as dividends; hence, its stock is a zero-growth stock. Its current cost of equity, r_s, is 14%. If it increases leverage, r_s will be 16%. If it decreases leverage, r_s will be 13%. What is the firm's WACC and total corporate value under each capital structure?

(15-10) Optimal Capital Structure with Hamada

Beckman Engineering and Associates (BEA) is considering a change in its capital structure. BEA currently has $20 million in debt carrying a rate of 8%, and its stock price is $40 per share with 2 million shares outstanding. BEA is a zero-growth firm and pays out all of its earnings as dividends. The firm's EBIT is $14.933 million, and it faces a 40% federal-plus-state tax rate. The market risk premium is 4%, and the risk-free rate is 6%. BEA is considering increasing its debt level to a capital structure with 40% debt, based on market values, and repurchasing shares with the extra money that it borrows. BEA will have to retire the old debt in order to issue new debt, and the rate on the new debt will be 9%. BEA has a beta of 1.0.

a. What is BEA's unlevered beta? Use market value D/S (which is the same as w_d/w_s) when unlevering.
b. What are BEA's new beta and cost of equity if it has 40% debt?
c. What are BEA's WACC and total value of the firm with 40% debt?

(15-11) WACC and Optimal Capital Structure

F. Pierce Products Inc. is considering changing its capital structure. F. Pierce currently has no debt and no preferred stock, but it would like to add some debt to take advantage of low interest rates and the tax shield. Its investment banker has indicated that the pre-tax cost of debt under various possible capital structures would be as follows:

Market Debt-to-Value Ratio (w_d)	Market Equity-to-Value Ratio (w_s)	Market Debt-to-Equity Ratio (D/S)	Before-Tax Cost of Debt (r_d)
0.0	1.0	0.00	6.0%
0.2	0.8	0.25	7.0
0.4	0.6	0.67	8.0
0.6	0.4	1.50	9.0
0.8	0.2	4.00	10.0

F. Pierce uses the CAPM to estimate its cost of common equity, r_s and at the time of the analysis the risk-free rate is 5%, the market risk premium is 6%, and the company's tax rate is 40%. F. Pierce estimates that its beta now (which is "unlevered" because it currently has no debt) is 0.8. Based on this information, what is the firm's optimal capital structure, and what would be the weighted average cost of capital at the optimal capital structure?

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(15-12) Equity Viewed as an Option

A. Fethe Inc. is a custom manufacturer of guitars, mandolins, and other stringed instruments and is located near Knoxville, Tennessee. Fethe's current value of operations, which is also its value of debt plus equity, is estimated to be $5 million. Fethe has $2 million face value, zero coupon debt that is due in 2 years. The risk-free rate is 6%, and the standard deviation of returns for companies similar to Fethe is 50%. Fethe's owners view their equity investment as an option and they would like to know the value of their investment.

a. Using the Black-Scholes option pricing model, how much is Fethe's equity worth?
b. How much is the debt worth today? What is its yield?
c. How would the equity value and the yield on the debt change if Fethe's managers could use risk management techniques to reduce its volatility to 30%? Can you explain this?

SPREADSHEET PROBLEMS

(15-13) Build a Model: WACC and Optimal Capital Structure

resource

Start with the partial model in the file ***Ch15 P13 Build a Model.xlsx*** on the textbook's Web site. Reacher Technology has consulted with investment bankers and determined the interest rate it would pay for different capital structures, as shown in the following table. Data for the risk-free rate, the market risk premium, an estimate of Reacher's unlevered beta, and the tax rate are also shown. Based on this information, what is the firm's optimal capital structure, and what is the weighted average cost of capital at the optimal structure?

Percent Financed with Debt (w_d)	Before-Tax Cost Debt (r_d)
0%	6.0%
10	6.1
20	7.0
30	8.0
40	10.0
50	12.5
60	15.5
70	18.0

Input Data	
Risk-free rate	4.5%
Market risk premium	5.5%
Unlevered beta	0.8
Tax rate	40.0%

(15-14) Build a Model: Equity Viewed as an Option

resource

Higgs Bassoon Corporation is a custom manufacturer of bassoons and other wind instruments. Its current value of operations, which is also its value of debt plus equity, is estimated to be $200 million. Higgs has zero coupon debt outstanding that matures in 3 years with $110 million face value. The risk-free rate is 5%, and the standard deviation of returns for similar companies is 60%. The owners of Higgs Bassoon view their equity investment as an option and would like to know its value. Start with the partial model in the file ***Ch15 P14 Build a Model.xlsx*** on the textbook's Web site, and answer the following questions:

a. Using the Black-Scholes option pricing model, how much is the equity worth?
b. How much is the debt worth today? What is its yield?
c. How would the equity value change if the company used risk management techniques to reduce its volatility to 45%? Can you explain this?
d. Graph the cost of debt versus the face value of debt for values of the face value from $10 to $160 million.
e. Graph the values of debt and equity for volatilities from 0.10 to 0.90 when the face value of the debt is $100 million.

MINI CASE

Assume you have just been hired as a business manager of PizzaPalace, a regional pizza restaurant chain. The company's EBIT was $50 million last year and is not expected to grow. The firm is currently financed with all equity, and it has 10 million shares outstanding. When you took your corporate finance course, your instructor stated that most firms' owners would be financially better off if the firms used some debt. When you suggested this to your new boss, he encouraged you to pursue the idea. As a first step, assume that you obtained from the firm's investment banker the following estimated costs of debt for the firm at different capital structures:

Percent Financed with Debt, w_d	r_d
0%	—
20	8.0%
30	8.5
40	10.0
50	12.0

If the company were to recapitalize, then debt would be issued and the funds received would be used to repurchase stock. PizzaPalace is in the 40% state-plus-federal corporate tax bracket, its beta is 1.0, the risk-free rate is 6%, and the market risk premium is 6%.

a. Using the free cash flow valuation model, show the only avenues by which capital structure can affect value.
b. (1) What is business risk? What factors influence a firm's business risk?
   (2) What is operating leverage, and how does it affect a firm's business risk? Show the operating break-even point if a company has fixed costs of $200, a sales price of $15, and variable costs of $10.
c. Now, to develop an example that can be presented to PizzaPalace's management to illustrate the effects of financial leverage, consider two hypothetical firms: Firm U, which uses no debt financing, and Firm L, which uses $10,000 of 12% debt. Both firms have $20,000 in assets, a 40% tax rate, and an expected EBIT of $3,000.
   (1) Construct partial income statements, which start with EBIT, for the two firms.
   (2) Now calculate ROE for both firms.
   (3) What does this example illustrate about the impact of financial leverage on ROE
d. Explain the difference between financial risk and business risk.
e. What happens to ROE for Firm U and Firm L if EBIT falls to $2,000? What does this imply about the impact of leverage on risk and return?
f. What does capital structure theory attempt to do? What lessons can be learned from capital structure theory? Be sure to address the MM models.
g. What does the empirical evidence say about capital structure theory? What are the implications for managers?
h. With the preceding points in mind, now consider the optimal capital structure for PizzaPalace.
   (1) For each capital structure under consideration, calculate the levered beta, the cost of equity, and the WACC.
   (2) Now calculate the corporate value for each capital structure.

i. Describe the recapitalization process and apply it to PizzaPalace. Calculate the resulting value of the debt that will be issued, the resulting market value of equity, the price per share, the number of shares repurchased, and the remaining shares. Considering only the capital structures under analysis, what is PizzaPalace's optimal capital structure?
j. Suppose there is a large probability that L will default on its debt. For the purpose of this example, assume that the value of L's operations is $4 million (the value of its debt plus equity). Assume also that its debt consists of 1-year, zero coupon bonds with a face value of $2 million. Finally, assume that L's volatility, σ, is 0.60 and that the risk-free rate r_{RF} is 6%.
k. What is the value of L's stock for volatilities between 0.20 and 0.95? What incentives might the manager of L have if she understands this relationship? What might debtholders do in response?
l. How do companies manage the maturity structure of their debt?

SELECTED ADDITIONAL CASES

The following cases from CengageCompose cover many of the concepts discussed in this chapter and are available at **http://compose.cengage.com.**

Klein-Brigham Series:
Case 9, "Kleen Kar, Inc."; Case 43, "Mountain Springs, Inc."; and Case 57, "Greta Cosmetics, Inc.," each present a situation similar to the Strasburg example in the text. Case 74, "The Western Company"; and Case 99, "Moore Plumbing Supply," explore capital structure policies.

Brigham-Buzzard Series:
Case 8, "Powerline Network Corporation (Operating Leverage, Financial Leverage, and the Optimal Capital Structure)."

CHAPTER 16

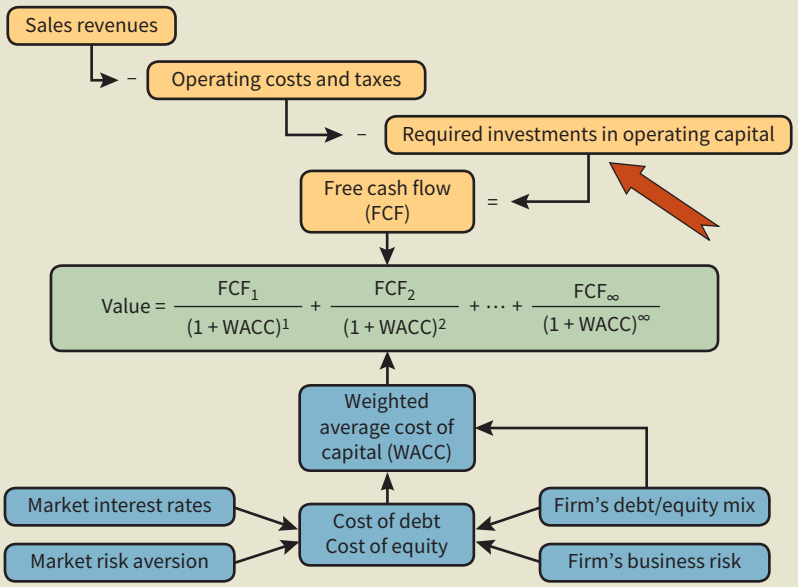
Supply Chains and Working Capital Management

What do Southwest Airlines, Apple, Qualcomm, and Family Dollar Stores have in common? Each led its industry in the *CFO Magazine* annual survey of working capital management, which covered the 1,000 largest U.S. publicly traded firms. Each company is rated on its "days of working capital," which is the amount of net operating working capital required per dollar of daily sales:

$$\text{Days of working capital (DWC)} = \frac{\text{Receivables} + \text{Inventory} - \text{Payables}}{\text{Average daily sales}}$$

The median industry ratio varies significantly. For example, the median in the computer and peripherals industry is 43, but the median in machinery is 82. The median airline holds zero days of working capital—its payables are as large as its combined receivables and inventory. But even within an industry, there is considerable variation. For example, Family Dollar has 16 days but Nordstrom has 79.



After being burned in the recent recession, many companies are holding record amounts of cash and have been accused by analysts of losing their focus on working capital. Not so with Thomson Reuters, a world leader in the news and data businesses, however. Thomson Reuters doesn't have much inventory and is hampered in reducing its receivables because it operates in so many different countries, so instead it focused on standardizing its global accounts payable policies and improved its DSO (days sales outstanding) by 3 days. When asked about the cash that other companies could possibly wring out of their working capital, Thomson Reuters's CFO Bob Daleo said, "Instead of giving it to their vendors and customers, why don't they give it back to their shareholders?" Keep this in mind as you read this chapter.

Corporate Valuation and Working Capital Management

Superior working capital management can dramatically reduce required investments in operating capital, which can lead, in turn, to larger free cash flows and greater firm value.

Working capital management involves two basic questions: (1) What is the appropriate amount of working capital, both in total and for each specific account? (2) How should working capital be financed? Note that sound working capital management goes beyond finance. Indeed, improving the firm's working capital position generally comes from improvements in the operating divisions. For example, experts in logistics, operations management, and information technology often work with engineers and production specialists to develop ways to speed up the manufacturing process and thus reduce the goods-in-process inventory. Similarly, marketing managers and logistics experts cooperate to develop better ways to deliver the firm's products to customers. Finance comes into play in evaluating how effective the firm's operating departments are relative to other firms in its industry and also in evaluating the profitability of alternative proposals for improving working capital management. In addition, financial managers decide how much cash their companies should keep on hand and how much short-term financing should be used to finance their working capital.

resource

The textbook's Web site contains an Excel *file that will guide you through the chapter's calculations. The file for this chapter is* ***Ch16 Tool Kit.xlsx****, and we encourage you to open the file and follow along as you read the chapter.*

16-1 Overview of Supply Chain Management

A **supply chain** consists of the network of organizations that convert materials and labor into products or services that ultimately are purchased by consumers. A requirement for effective supply chain management (SCM) is sharing information throughout the chain, all the way from retailers (where consumers make purchases) to wholesalers, to manufacturers, to suppliers, and even back to the suppliers' suppliers. SCM requires special computer software, but even more importantly, it requires cooperation among the different companies and departments in the supply chain.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Consider some of the activities involved in the supply chain of a company that purchases materials, adds value, and then sells the product. The company places an order with a supplier. The supplier ships the order and bills the company. The company either pays immediately or waits, in which case the unpaid amount is called an **account payable**. The newly arrived shipment goes into inventory until it is needed. If the supplier shipped finished products, the company will distribute the goods to its warehouses or retail facilities. If instead the supplier shipped components or raw materials, the company will use the shipment in a manufacturing or assembly process, putting the final product into its finished goods inventory. Items from the finished goods inventory will be shipped either directly to customers or to warehouses for later shipments.

When a customer purchases the product, the company bills the customer and often offers the customer credit. If the customer accepts the credit and doesn't pay immediately, the unpaid balance is called an **account receivable**.[1] At the time a credit sale is made, three events occur: (1) Inventories are reduced by the cost of goods sold. (2) Accounts receivable are increased by the sales price. (3) The difference between the amounts that receivables increase and that inventories decrease is reported immediately as pre-tax profit (even though cash has not yet been received), adjusted for taxes, and then added to the previous retained earnings balance.

If the sale were instead for cash, then the scenario just described would accurately describe cash flow. However, a firm will not receive cash from a credit sale unless and until the account is collected. Firms have been known to encourage credit "sales" to weak customers in order to report high current profits. This might boost the firm's stock price—but only for a short time. Eventually, future credit losses will reduce earnings, at which time the stock price will fall. This is another example of how differences between a firm's stock price and its intrinsic value can arise.

During this supply chain process, companies accrue unpaid wages (because companies don't pay employees daily) and unpaid taxes (because companies don't pay the IRS daily).

Notice that several current assets and current liabilities are involved in this process—*cash* is spent (when actually paying suppliers, employees, taxes, etc.) and collected (when customers pay), *accounts receivable* are created and collected, *inventory* ebbs and flows, *accounts payable* are generated and paid, and *accruals* accumulate until paid. Notice that these are the same operating current assets (cash, accounts receivable, and inventories) and operating current liabilities (accounts payable and accruals) that we have used in previous chapters when calculating **net operating working capital (NOWC)**, which is defined as operating current assets minus operating current liabilities.

In addition to operating current assets and operating current liabilities, there are two other current accounts related to working capital management: short-term investments and short-term debt. We discuss individual current assets and liabilities later in the chapter, but it will be helpful if we first distinguish between cash and short-term investments because this can be a source of confusion.

Many dictionaries define cash as currency (coins and bills) and demand deposit accounts (such as a checking account at a bank). Most companies have very little currency on hand, and most have relatively small checking accounts. However, most companies own a wide variety of short-term financial assets. For example, Apple and Microsoft own: (1) checking accounts, (2) U.S. Treasury and agency securities, (3) certificates of deposits and time deposits, (4) commercial paper, (5) money market funds and other mutual funds (with low price volatility), (6) short-term or floating-rate corporate and municipal notes and bonds, and (7) and floating-rate preferred stock. Most of these holdings can be

[1]For every account receivable recorded by a seller (which is a current asset), an equal account payable is recorded by the purchaser (which is a liability).

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

converted into cash very quickly at prices identical or very close to their book values, so sometimes they are called cash equivalents.

Some of these financial assets are held to support current ongoing operations and some are held for future purposes, and this is the distinction we make when defining cash and short-term investments. In particular, we define cash as the total value of the short-term financial assets that are held to support ongoing operations because this is the definition of cash that is required to be consistent with the definition of cash used to calculate NOWC (which is used, in turn, to calculated free cash flow and the intrinsic value of the company). We define short-term investments as the total value of short-term financial assets held for future purposes. Keep these distinctions in mind when we discuss cash management and short-term investments later in the chapter.

You should be aware that the financial press isn't as careful with its definitions. For example, the press often uses **working capital** (or *gross working capital*) to denote current assets used in operations, which ignores the impact operating current liabilities have on cash flow.[2] The press also uses **net working capital** to denote *all* current assets minus *all* current liabilities, which mixes operating measures with financing choices. We prefer the term "net operating working capital (NOWC)" because it is directly related to free cash flow from operations.

16-2 Using and Financing Operating Current Assets

Operating current assets (CA) are used to support sales. Having too much invested in operating CA is inefficient, but having too little might constrain sales. Many companies have seasonal, growing sales, so they have seasonal, growing operating CA, which has an implication for the pattern of financing that companies choose. The next sections address these issues.

16-2a Efficient Investment in Operating Current Assets

Most companies can influence their ratios of operating current assets to sales. Some companies choose a **relaxed policy** and hold a lot of cash, receivables, and inventories relative to sales. On the other hand, if a firm has a **restricted policy**, holdings of current assets are minimized and we say that the firm's policy is *tight* or *"lean-and-mean."* A **moderate policy** lies between the two extremes.

We can use the DuPont equation from Chapter 3 to demonstrate how working capital management affects the return on equity:

$$\begin{aligned}\text{ROE} &= \text{Profit margin} \times \text{Total assets turnover} \times \text{Equity multiplier} \\ &= \text{Profit margin} \times \frac{\text{Sales}}{\text{Assets}} \times \text{Equity multiplier}\end{aligned}$$

A relaxed policy means a high level of assets and hence a low total assets turnover ratio; this results in a low return on equity (ROE), other things held constant. Conversely, a restricted policy results in low current assets, a high turnover, and hence a relatively high ROE. However, the restricted policy exposes the firm to risk, because shortages can lead to work stoppages, unhappy customers, and serious long-run problems.

[2]The term "working capital" originated with the old Yankee peddler, who would load his wagon with pots and pans and then take off to peddle his wares. His horse and wagon were his fixed assets, while his merchandise was sold, or turned over at a profit, and thus was called his *working capital*.

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

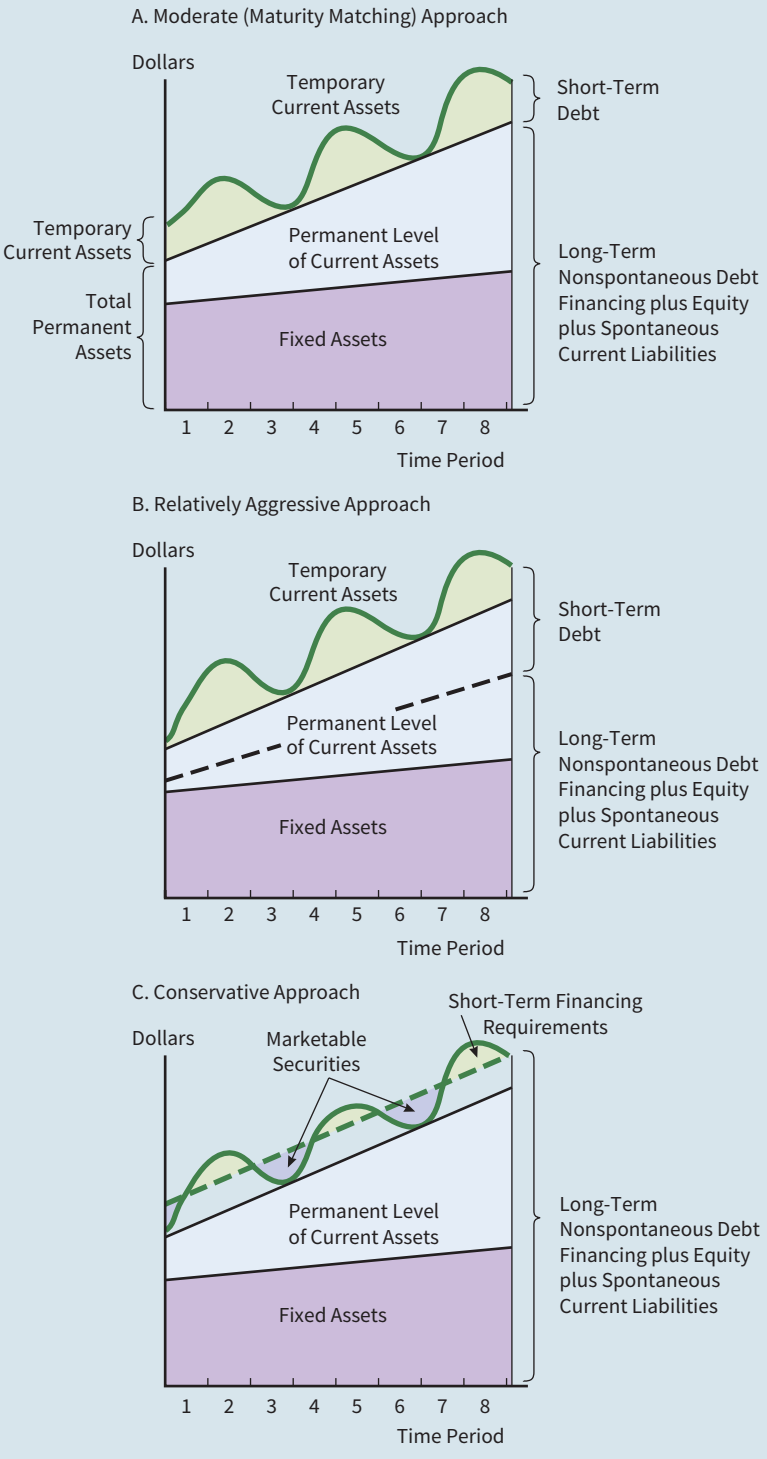
The moderate policy falls between the two extremes. The optimal strategy is the one that management believes will maximize the firm's long-run free cash flow and thus the stock's intrinsic value.

Note that changing technologies can lead to changes in the optimal policy. For example, if a new technology makes it possible for a manufacturer to produce a given product in 5 rather than 10 days, then work-in-progress inventories can be cut in half. Similarly, most retailers have inventory management systems that use bar codes on all merchandise. These codes are read at the cash register; this information is transmitted electronically to a computer that adjusts the remaining stock of the item; and the computer automatically places an order with the supplier's computer when the supply falls to a specified level. This process lowers the "safety stocks" that would otherwise be necessary to avoid running out of stock. Such systems have dramatically lowered inventories and thus boosted profits.

16-2b Financing Operating Current Assets

Investments in operating current assets must be financed, and the primary sources of funds include bank loans, credit from suppliers (accounts payable), accrued liabilities, long-term debt, and common equity. Each of those sources has advantages and disadvantages, so a firm must decide which sources are best for it.

To begin, note that most businesses experience seasonal and/or cyclical fluctuations. For example, construction firms tend to peak in the summer, retailers peak around Christmas, and the manufacturers who supply both construction companies and retailers follow related patterns. Similarly, the sales of virtually all businesses increase when the economy is strong, so they increase operating current assets during booms but let inventories and receivables fall during recessions. However, current assets rarely drop to zero—companies maintain some **permanent operating current assets**, which are the operating current assets needed even at the low point of the business cycle. For a growing firm in a growing economy, permanent current assets tend to increase over time. Also, as sales increase during a cyclical upswing, current assets are increased; these extra current assets are defined as **temporary operating current assets** as opposed to permanent current assets. The way permanent and temporary operating current assets are financed is called the firm's **operating current assets financing policy**. Three alternative policies are discussed next.



MATURITY MATCHING APPROACH

The **maturity matching approach**, which is also called the **self-liquidating approach**, calls for matching asset and liability maturities as shown in Panel A of Figure 16-1. All of the fixed assets plus the permanent current assets are financed with long-term capital, but temporary current assets are financed with short-term debt. Inventory expected to be sold in 30 days would be financed with a 30-day bank loan; a machine expected to last for 5 years would be financed with a 5-year loan; a 20-year building would be financed with a 20-year mortgage bond; and so on.

Actually, two factors prevent exact maturity matching: uncertain asset lives and equity financing. For example, a firm might finance inventories with a 30-day bank loan, expecting to sell the inventories and use the cash to retire the loan. But if sales are slow, then the "life" of the inventories would exceed the original 30-day estimate and the cash from sales would not be forthcoming, perhaps causing the firm problems in paying off the loan when it comes due. In addition, some common equity financing must be used, and common equity has no maturity. Still, many firms adopt a short-term financing policy that comes close to matching asset and liability maturities.

AGGRESSIVE APPROACH

Panel B of Figure 16-1 illustrates the **aggressive approach** in which a firm finances some of its permanent assets with short-term debt. Note that we used the term "relatively" in the title for Panel B because there can be different *degrees* of aggressiveness. For example, the dashed line in Panel B could have been drawn *below* the line designating fixed assets, indicating that all of the current assets—both permanent and temporary—and part of the fixed assets were financed with short-term credit. This policy would be highly aggressive, and the firm would be subject to dangers from loan renewal as well as rising interest rates. However, short-term interest rates are generally lower than long-term rates, and some firms are willing to gamble by using a large amount of low-cost, short-term debt in hopes of earning higher profits.

A possible reason for adopting the aggressive policy is to take advantage of an upward-sloping yield curve, for which short-term rates are lower than long-term rates. However, as many firms learned during the financial crisis of 2007, a strategy of financing long-term assets with short-term debt is really quite risky. As an illustration, suppose a company borrowed $1 million on a 1-year basis and used the funds to buy machinery that would lower labor costs by $200,000 per year for 10 years.[3] Cash flows from the equipment would not be sufficient to pay off the loan at the end of only 1 year, so the loan would have to be renewed. If the economy were in a recession like that of 2007, the lender might refuse to renew the loan, and that could lead to bankruptcy. Had the firm matched maturities and financed the equipment with a 10-year loan, then the annual loan payments would have been lower and better matched with the cash flows, and the loan renewal problem would not have arisen.

Under some circumstances, even maturity matching can be risky, as many firms that thought they were conservatively financed learned in 2007. If a firm borrowed on a 30-day bank loan to finance inventories that it expected to sell within 30 days but then sales dropped, as they did for many firms in 2007, the funds needed to pay off the maturing bank loan might not be available. If the bank would not extend the loan, then the firm could be forced into bankruptcy. This happened to many firms in 2007, and it was exacerbated by the banks' own problems. The banks lost billions on mortgages, mortgage-backed bonds, and other bad investments, which led them to restrict credit to their normal business customers in order to conserve their own cash.

CONSERVATIVE APPROACH

Panel C of the figure shows the **conservative approach**, with the dashed line *above* the line designating permanent current assets. In this approach, long-term capital is used to finance all permanent assets and also to meet some seasonal needs. The firm uses a small amount of short-term credit to meet its peak requirements, but it also meets a part of its seasonal needs by "storing liquidity" in the form of marketable securities. The humps above the dashed line represent short-term financings, while the troughs below the dashed line represent short-term security holdings. This conservative financing policy is fairly safe, and the wisdom of using it was demonstrated in 2007—when credit dried up, firms with adequate cash holdings were able to operate more effectively than those that were forced to cut back their operations because they couldn't order new inventories or pay their normal workforce.

[3]We are oversimplifying here. Few lenders would explicitly lend money for 1 year to finance a 10-year asset. What would actually happen is that the firm would borrow on a 1-year basis for "general corporate purposes" and then actually use the money to purchase the 10-year machinery.

CHOOSING AMONG THE APPROACHES

Because the yield curve is normally upward sloping, *the cost of short-term debt is generally lower than that of long-term debt*. However, *short-term debt is riskier for the borrowing firm* for two reasons: (1) If a firm borrows on a long-term basis, then its interest costs will be relatively stable over time, but if it uses short-term credit, then its interest expense can fluctuate widely—perhaps reaching such high levels that profits are extinguished.[4] (2) If a firm borrows heavily on a short-term basis, then a temporary recession may adversely affect its financial ratios and render it unable to repay its debt. Recognizing this fact, the lender may not renew the loan if the borrower's financial position is weak, which could force the borrower into bankruptcy.

Note also that *short-term loans can generally be negotiated much faster* than long-term loans. Lenders need to make a thorough financial examination before extending long-term credit, and the loan agreement must be spelled out in great detail because a lot can happen during the life of a 10- to 20-year loan.

Finally, *short-term debt generally offers greater flexibility*. If the firm thinks that interest rates are abnormally high and due for a decline, it may prefer short-term credit because prepayment penalties are often attached to long-term debt. Also, if its needs for funds are seasonal or cyclical, then the firm may not want to commit itself to long-term debt because of its underwriting costs and possible prepayment penalties. Finally, long-term loan agreements generally contain provisions, or *covenants,* that constrain the firm's future actions in order to protect the lender, whereas short-term credit agreements generally have fewer restrictions.

All things considered, it is not possible to state that either long-term or short-term financing is generally better. The firm's specific conditions will affect its decision, as will the risk preferences of managers. Optimistic and/or aggressive managers will lean more toward short-term credit to gain an interest cost advantage, whereas more conservative managers will lean toward long-term financing to avoid potential renewal problems. The factors discussed here should be considered, but the final decision will reflect managers' personal preferences and subjective judgments.

SELF-TEST

Identify and explain three alternative current asset investment policies.

Use the DuPont equation to show how working capital policy can affect a firm's expected ROE.

What are the reasons for not wanting to hold too little working capital? For not wanting to hold too much?

Differentiate between permanent operating current assets and temporary operating current assets.

What does maturity matching mean, and what is the logic behind this policy?

What are some advantages and disadvantages of short-term versus long-term debt?

16-3 The Cash Conversion Cycle

All firms follow a "working capital cycle" in which they purchase or produce inventory, hold it for a time, and then sell it and receive cash. This process is known as the **cash conversion cycle (CCC)**.

[4]The prime interest rate—the rate banks charge very good customers—hit 21% in the early 1980s. This produced a level of business bankruptcies that was not seen again until 2009. The primary reason for the very high interest rate was that the inflation rate was up to 13%, and high inflation must be compensated by high interest rates. Also, the Federal Reserve was tightening credit in order to hold down inflation, and it was encouraging banks to restrict their lending.

16-3a Calculating the Target CCC

Assume that Great Basin Medical Equipment (GBM) buys medical devices from manufacturers in China and sells them in the United States, Canada, and Mexico. On average, it is 50 days from the time GBM purchases merchandise ($10 million a month) until the time GBM sells to its customers. GBM's suppliers require payment within 40 days, but GBM gives its customers 60 days to pay for their purchases.

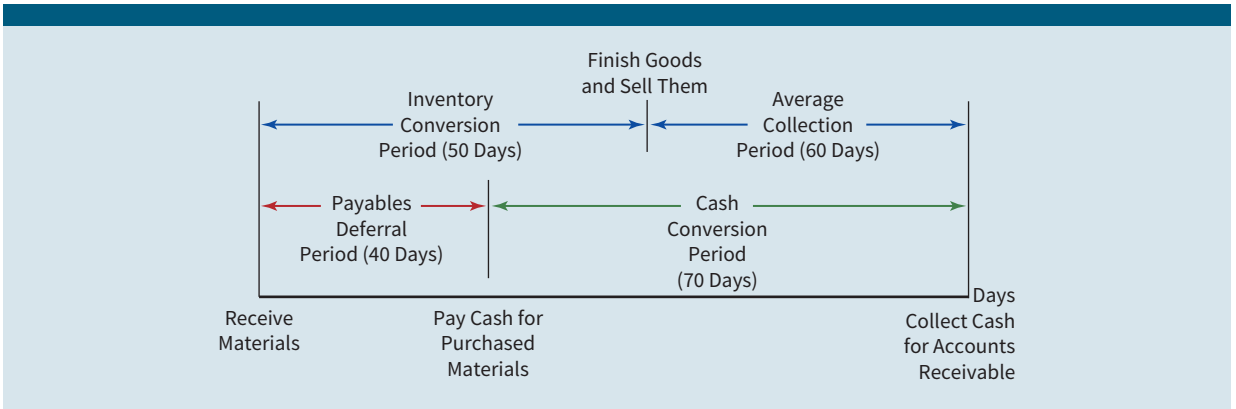
GBM's target cash conversion cycle shows the *net* amount of time between GBM's payments to suppliers and GBM's collections from customers. The cash conversion cycle has a big impact on GBM's financing costs because GBM takes out bank loans to cover cash shortfalls during this cycle. The following definitions are used in calculating the cycle length.

1. **Inventory conversion period (ICP)**. This is the length of time between purchasing material or merchandise from suppliers and recording a sale to customers (which creates an account receivable because GBM offers credit to its customers). GBM's target is 50 days.[5]
2. **Average collection period (ACP)**. This is the length of time customers are given to pay for goods following a sale. The ACP is also called the **days sales outstanding (DSO)**. GBM's business plan calls for an ACP of 60 days based on its 60-day credit terms. This is also called the **receivables conversion period** because it's the number of days required to convert receivables into cash.
3. **Payables deferral period (PDP)**. This is the length of time a supplier allows customer to defer payment after making a purchase. GBM's suppliers allow it 40 days.

On Day 1, GBM expects to buy merchandise, and it expects to sell the goods and thus convert them to accounts receivable within 50 days. It should then take 60 days to collect the receivables, making a total of 110 days between receiving merchandise and collecting cash. However, GBM is able to defer its own payments for only 40 days. The net number of days in GBM's target cash conversion cycle is shown in the following formula:

$$\begin{aligned}\text{Cash conversion cycle} &= \text{Inventory conversion period} + \text{Average collection period} - \text{Payables deferral period} \quad \textbf{(16-1)}\\ &= 50 + 60 - 40\\ &= 70 \text{ days}\end{aligned}$$

Figure 16-2 diagrams the activities represented in Equation 16-1. Notice that GBM has a 70-day cash shortfall that it must finance during the cycle.



Although GBM is supposed to pay its suppliers $10 million after 40 days, it does not expect to receive any cash until 110 days into the cycle: $50 + 60 = 110$. Therefore, it will have to borrow the $10 million cost of merchandise from its bank on Day 40, and it does not expect to be able to repay the loan until it collects on Day 110. Thus, during its 70-day $(110 - 40 = 70)$ target cash conversion cycle, it will owe the bank $10 million and accrue interest on this debt. All else equal, a shorter cash conversion cycle is preferable, because a shorter CCC means lower interest charges.

Observe that if GBM could sell goods faster, collect receivables faster, or defer its payables longer without hurting sales or increasing operating costs, then its CCC would decline, its expected interest charges would be reduced, and its expected net income would increase.

[5]If GBM were a manufacturer, the inventory conversion period would be the time required to convert raw materials into finished goods and then to sell those goods.

FIGURE 16-2
The Cash Conversion Cycle

16-3b Calculating the Actual Cash Conversion Cycle from Financial Statements

Instead of using *target* values, let's calculate GBM's *actual* cash conversion cycle. The following data were taken from its latest financial statements:

Selected Data (Millions of Dollars)	
Annual sales	$150
Cost of goods sold	122
Inventories	17
Accounts receivable	51
Accounts payable	13

We begin by calculating GBM's actual inventory conversion period. Financial statements record inventory at cost, so we divide inventory by the daily cost of goods sold (and not sales) when calculating the inventory conversion period:

$$\text{Inventory conversion period (ICP)} = \frac{\text{Inventory}}{\text{Cost of goods sold per day}} \quad \textbf{(16-2)}$$

$$= \frac{\$17}{\$122/365} = 50.9 \text{ days}$$

Thus, it takes GBM 50.9 days to convert inventory into sales, which is very close to its 50-day target.

Receivables are recorded at the sales price because they reflect the cash that is forgone by offering credit to customer. Therefore, we use daily sales (rather than the cost of goods sold per day) to calculate GBM's average collection period:

$$\text{Average collection period (ACP or DSO)} = \frac{\text{Receivables}}{\text{Sales}/365} \quad \textbf{(16-3)}$$

$$= \frac{\$51}{\$150/365} = 124.1 \text{ days}$$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Notice that GBM actually takes 124.1 days after a sale to receive cash, which is much higher than its 60-day target.

In contrast to receivables, accounts payable are recorded at purchase price because this reflects the cash payments that can be deferred by accepting credit from the supplier. Therefore, we divide payables by the daily cost of goods sold (and not sales) when calculating the payables deferral period:

$$\text{Payables deferral period (PDP)} = \frac{\text{Payables}}{\text{Daily purchases}} = \frac{\text{Payables}}{\text{Cost of goods sold}/365} \quad \textbf{(16-4)}$$

$$= \frac{\$13}{\$122/365} = 38.9 \text{ days}$$

GBM is supposed to pay its suppliers within 40 days, and it is doing so.

We can use Equation 16-1 and the previously calculated individual periods to determine GBM's actual cash conversion cycle:

$$\text{Cash conversion cycle (CCC)} = 50.9 \text{ days} + 124.1 \text{ days} - 38.9 \text{ days} = 136.1 \text{ days}$$

Figure 16-3 summarizes the previous calculations and shows that GBM's inventory management and purchasing payment systems are performing as expected. However, its

receivables are much higher than targeted, indicating that customers are not paying on time. In fact, they are taking over twice as long to pay as GBM expects. This delay hurts GBM's free cash flows, increases its interest expense, and reduces debt capacity that could be used elsewhere in the company.

16-3c Benefits of Reducing the Cash Conversion Cycle

Later sections provide more detailed analyses of changes in inventory management, receivables management, and payables management, but let's look at the big picture right now. Suppose GBM can improve its business processes so that it can reduce the inventory conversion period to 35 days and the average collection period to 40 days. In addition, suppose GBM can negotiate an extension in the suppliers' payment terms to 50 days. The "New Target" column of Figure 16-4 shows the effects of these changes.

As shown in Figure 16-4, GBM's current actual cash conversion cycle is 136.1 days, with the net operating working capital financed during this period by a bank loan charging a 10% annual rate. With an average annual level of $55 million in NOWC, the annual interest paid on the bank loan is $5.5 million: 10%($55) = $5.5. Figure 16-4 shows that NOWC would drop to $11.4 million if GBS can implement the improvements, which would cut the interest expense to about $1.14 million.

Recall from previous chapters that free cash flow (FCF) is equal to net operating profit after taxes (NOPAT) minus the investment in total net operating capital. Therefore, if working capital *decreases* by a given amount while all else remains constant, then FCF

increases by that same amount. For GBM, free cash flow would increase $43.6 million ($55.0 − $11.4 = $43.6). If sales remained constant in the following years, then this reduction in working capital would be a one-time cash inflow only. However, suppose sales grow in future years. When a company improves its working capital management, the components (inventory conversion period, collection period, and payments period) usually remain at their improved levels, which means the NOWC-to-Sales ratio remains at its new level. With an improved NOWC-to-Sales ratio, less working capital will be required to support future sales, leading to higher annual FCFs than would have otherwise existed.

Thus, an improvement in working capital management creates a large one-time increase in FCF at the time of the improvement as well as higher FCF in future years. Therefore, an improvement in working capital management is a gift that keeps on giving.

These benefits can add substantial value to the company. Professors Hyun-Han Shin and Luc Soenen studied more than 2,900 companies over a 20-year period, finding a strong relationship between a company's cash conversion cycle and its stock performance.[6] For an average company, a 10-day improvement in its CCC was associated with an increase in pre-tax operating profit margin from 12.76% to 13.02%. Moreover, companies with cash conversion cycles 10 days shorter than the average for their industry had annual stock returns that were 1.7 percentage points higher than the average company. Given results like these, it's no wonder firms place so much emphasis on reducing working capital through improved supply chain management![7]

SELF-TEST

Define the following terms: inventory conversion period, average collection period, and payables deferral period. Give the equation for each term.

What is the cash conversion cycle? What is its equation?

What should a firm's goal be regarding the cash conversion cycle, holding other things constant? Explain your answer.

What are some actions a firm can take to shorten its cash conversion cycle?

A company has $20 million of inventory, $5 million of receivables, and $4 million of payables. Its annual sales revenue is $80 million, and its cost of goods sold is $60 million. What is its CCC? **(120.15)**

Some Firms Operate with Negative Working Capital!

Some firms are able to operate with zero or even negative net working capital. Dell Computer and Amazon are examples. When customers order computers from Dell's Web site or books from Amazon, they must provide a credit card number. Dell and Amazon then receive next-day cash, even before the product is shipped and even before they have paid their own suppliers. This results in a negative CCC, which means that working capital *provides* cash rather than *uses* it.

In order to grow, companies normally need cash for working capital. However, if the CCC is negative, then growth in sales *provides* cash rather than *uses* it. This cash can be invested in plant and equipment, research and development, or for any other corporate purpose. Analysts recognize this point when they value Dell and Amazon, and it certainly helps their stock prices.

16-4 Inventory Management

Inventory management techniques are covered in depth in production management courses. Still, financial managers have a responsibility for raising the capital needed to carry inventory and for overseeing the firm's overall profitability, so it is appropriate that we cover the financial aspects of inventory management here.

The twin goals of inventory management are: (1) ensuring that the inventories needed to sustain operations are available, while (2) holding the costs of ordering and carrying inventories to the lowest possible level. In analyzing improvements in the cash conversion cycle, we identified some of the cash flows associated with a reduction in inventory. In addition to the points made earlier, lower inventory levels reduce costs due to storage and handling, insurance, property taxes, spoilage, and obsolescence.

Before the computer age, companies used simple inventory control techniques such as the **red line** system, where a red line was drawn around the inside of a bin holding inventory items; when the actual stock declined to the level where the red line showed, inventory would be reordered. Now computers have taken over, and supply chains have been established that provide inventory items just before they are needed—the **just-in-time (JIT)** system. For example, consider Trane Corporation, which makes air conditioners and currently uses just-in-time procedures. In the past, Trane produced parts on a steady basis, stored them as inventory, and had them ready whenever the company received an order for a batch of air conditioners. However, the company's inventory eventually covered an area equal to three football fields, and it still could take as long as 15 days to fill an order. To make matters worse, occasionally some of the necessary components simply could not be located; in other instances, the components were located but found to have been damaged from long storage.

Then Trane adopted a new inventory policy—it began producing components only after receiving an order and then sending the parts directly from the machines that make them to the final assembly line. The net effect: Inventories fell nearly 40% even as sales were increasing by 30%.

Such improvements in inventory management can free up considerable amounts of cash. In the last section, we examined inventory reductions due to improvements in the inventory conversion period. Many analysts also use the inventory turnover ratio as a performance measure, so you should know how to estimate inventory reductions due to improvements in turnover. Recall from Chapter 3 that the inventory turnover ratio is defined as cost of goods sold (COGS) divided by inventory.[8] If we know the turnover ratio and the COGS, we can determine the inventory level. For example, suppose a company's inventory turnover ratio is 3 and its COGS is $120 million. Starting with the definition of the turnover ratio and solving for inventory yields:

$$\begin{aligned}\text{Inventory turnover ratio} &= \text{COGS}/\text{Inventory}\\ \text{Inventory} &= \text{COGS}/(\text{Inventory turnover ratio})\\ &= \$120/3 = \$40 \text{ million}\end{aligned}$$

If the company can improve its inventory turnover ratio to 4, then its inventory will fall to:

$$\text{Inventory} = \$120/4 = \$30 \text{ million}$$

This $10 million reduction in inventory ($\$40 - \$30 = \$10$) boosts free cash flow by $10 million.

[8]The relationship between the inventory conversion period and the inventory turnover ratio is: Inventory conversion period = 365/(Inventory turnover ratio).

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

However, there are costs associated with holding too little inventory, and these costs can be severe. If a business lowers its inventories, then it must reorder frequently, which increases ordering costs. Even worse, if stocks become depleted then firms can miss out on profitable sales and also suffer lost goodwill, which may lead to lower future sales. Therefore, it is important to have enough inventory on hand to meet customer demands but not so much as to incur the costs we discussed previously. Inventory optimization models have been developed, but the best approach—and the one most firms today are following—is to use supply chain management and monitor the system closely.[9]

SELF-TEST

What are some costs associated with high inventories? With low inventories?

What is a "supply chain," and how are supply chains related to just-in-time inventory procedures?

A company has $20 million in cost of goods sold and an inventory turnover ratio of 2.0. If it can reduce its inventory and improve its inventory turnover ratio to 2.5 with no loss in units sold and no change in cost of goods sold, by how much will FCF increase? **($2 million)**

16-5 Receivables Management

Firms would, in general, rather sell for cash than on credit, but competitive pressures force most firms to offer credit for substantial purchases, especially to other businesses. Thus, goods are shipped, inventories are reduced, and receivables are increased. Eventually, customers will pay their bills, at which time the firm's cash will increase and its receivables will decrease.[10] Carrying receivables has both direct and indirect costs, but selling on credit also has an important benefit—increased sales. Balancing these benefits and costs requires an effective credit policy and monitoring system, described in the following sections.[11]

16-5a Credit Policy

The success or failure of a business depends primarily on the demand for its products—as a rule, high sales lead to larger profits and a higher stock price. Sales, in turn, depend on a number of factors: Some, like the state of the economy, are exogenous, but others are under the firm's control. The major controllable factors are sales prices, product quality, advertising, and the firm's **credit policy**. Credit policy, in turn, consists of the following four variables:

1. **Credit period**. A firm might sell on terms of "net 30," which means that the customer must pay within 30 days.
2. **Cash discounts**. Some companies offer a percentage reduction in the sales price (called a **discount percentage**) if the purchaser pays in cash before the end of the

[9]For additional insights into the problems of inventory management, see Richard A. Followill, Michael Schellenger, and Patrick H. Marchard, "Economic Order Quantities, Volume Discounts, and Wealth Maximization," *The Financial Review*, February 1990, pp. 143–152.

[10]If the purchaser doesn't pay for the goods in a reasonable amount of time, the adjustments are more complicated and differ between public and tax accounting.

[11]For more on credit policy and receivables management, see Shehzad L. Mian and Clifford W. Smith, "Extending Trade Credit and Financing Receivables," *Journal of Applied Corporate Finance*, Spring 1994, pp. 75–84; and Paul D. Adams, Steve B. Wyatt, and Yong H. Kim, "A Contingent Claims Analysis of Trade Credit," *Financial Management*, Autumn 1992, pp. 104–112.

specified **discount period**. A company's **credit terms** specify the discount percentage, the discount period, and the full credit period. For example, "2/10, net 30" means that buyers may deduct 2% of the purchase price (the discount percentage) if payment is made within 10 days (the discount period); otherwise, the full amount must be paid within 30 days (the credit period). Cash discounts provide incentives for purchasers to make cash payments more quickly.

3. **Credit standards**. How much financial strength must a customer show to qualify for credit? Lower credit standards boost sales, but they also increase bad debts.
4. **Collection policy**. How tough or lax is a company in attempting to collect slow-paying accounts? A tough policy may speed up collections, but it might also anger customers and cause them to take their business elsewhere.

The credit manager is responsible for administering the firm's credit policy. However, because of the pervasive importance of credit, the credit policy itself is normally established by the executive committee, which usually consists of the president plus the vice presidents of finance, marketing, and production.

16-5b Credit Policy and the Accumulation of Receivables

Credit policies and customer behaviors determine the accumulation of accounts receivable. For example, suppose Boston Lumber Company (BLC), a wholesale distributor of lumber products, had always collected at the time of purchase. BLC had an average collection period of 0 days, but its sales were lower than they would have been if it offered credit sales. Several years ago BLC began offering credit sales on January 1 with the terms "net 30" and all customers bought on credit. Sales increased to $1,000 each day, but what impact did this have on accounts receivable?

At the end of the first day, accounts receivable were $1,000; they rose to $2,000 by the end of the second day; and by January 30, they were $30,000. On January 31, another $1,000 was added to receivables, but $1,000 in payments was collected for sales made on January 1. Therefore, the cumulative accounts receivable remained constant at $30,000. Netting out new credit sales and collections each day is accurate but tedious, so we show an easier method next.

We can rewrite Equation 16-3, solving for the level of accounts receivable:

$$\text{Accounts receivable} = \text{Sales per day} \times \text{Average collection period} \qquad (16\text{-}5)$$

BLC's daily sales were $1,000 and its average collection period increased from 0 to 30 days, so its receivables leveled off at:

$$\begin{aligned} \text{Accounts receivable} &= \text{Sales per day} \times \text{Average collection period} \\ &= \$1{,}000 \times 30 \\ &= \$30{,}000 \end{aligned}$$

Therefore, modifications in either daily credit sales or the collection period (due to changes in the credit terms or customer behavior) will change the accounts receivable balance, which in turn changes free cash flow.

16-5c Monitoring the Receivables Position

In the previous example, BLC's customers paid on time, but that is not always the case. Analysis along the lines suggested in the following sections can help detect potential problems before they become too serious.

CREDIT TERMS, CUSTOMER BEHAVIOR, AND THE DAYS SALES OUTSTANDING

Suppose Super Set Inc., a manufacturer of ultra-thin televisions, sells 219,000 sets a year at a price of $200 each. Assume that all sales are on credit under the terms 2/10, net 30. Finally, assume that 70% of the customers take the discount and pay on Day 10 and 30% pay on Day 30.[12]

Super Set's average collection period (ACP), which is also called days sales outstanding (DSO), is 16 days:

$$\begin{aligned}\text{Average collection period} = \text{DSO} &= 0.7(10 \text{ days}) + 0.3(30 \text{ days}) \\ &= 16 \text{ days}\end{aligned}$$

On average, Super Set sells $120,000 per day:

$$\text{Sales per day} = \frac{\text{Annual sales}}{365} = \frac{(\text{Units sold})(\text{Sales price})}{365}$$

$$= \frac{(219{,}000)(\$200)}{365} = \$120{,}000$$

Supply Chain Finance

In our global economy, companies purchase parts and materials from suppliers located all over the world. For small and mid-sized suppliers, especially those in less-developed economies, selling to international customers can lead to cash flow problems. First, many suppliers have no way of knowing when their invoices have been approved by their customers. Second, they have no way of knowing when they will actually receive payment from their customers. With a 4–5-month lag between the time an order is received and the time the payment occurs, many suppliers resort to expensive local financing that can add as much as 4% to their costs. Even worse, some suppliers go out of business, which reduces competition and ultimately leads to higher prices.

Although most companies work very hard with their suppliers to improve their supply chain operations—which is at the heart of supply management—a recent poll shows that only 13% actively use supply chain finance (SCF) techniques. However, that figure is likely to rise in the near future. For example, Big Lots joined a Web-based service operated by PrimeRevenue that works like this: First, invoices received by Big Lots are posted to the system as soon as they are approved. The supplier doesn't need specialized software but can check its invoices using a Web browser. Second, the supplier has the option of selling the approved invoices at a discount to financial institutions and banks that have access to the PrimeRevenue network. A further advantage to the supplier is that it receives cash within a day of the invoice's approval. In addition, the effective interest rate built into the discounted price is based on the credit rating of Big Lots, not that of the supplier.

As Big Lots treasurer Jared Poff puts it, this allows vendors to "compete on their ability to make the product and not on their ability to access financing."

Source: Kate O'Sullivan, "Financing the Chain," *CFO*, February 2007, pp. 46–53.

[12]Unless otherwise noted, we assume throughout that payments are made either on the *last day* for taking discounts or on the *last day* of the credit period. It would be foolish to pay on (say) the 5th day or on the 20th day if the credit terms were 2/10, net 30.

Using Equation 16-5 and recognizing that the average collection period is the same as the days sales outstanding, Super Set's accounts receivable—assuming a constant, uniform rate of sales throughout the year—will at any point in time be $1,920,000:

$$\text{Accounts receivable} = \text{Sales per day} \times \text{Days sales outstanding} \quad \textbf{(16-5a)}$$

$$= \$120{,}000 \times 16$$
$$= \$1{,}920{,}000$$

AGING SCHEDULES

An **aging schedule** breaks down a firm's receivables by age of account. Table 16-1 shows the December 31, 2016, aging schedules of two television manufacturers, Super Set and Wonder Vision. Both firms offer the same credit terms, and they have the same total receivables. Super Set's aging schedule indicates that all of its customers pay on time: 70% pay by Day 10 and 30% pay by Day 30. In contrast, Wonder Vision's schedule, which is more typical, shows that many of its customers are not paying on time: 27% of its receivables are more than 30 days old, even though Wonder Vision's credit terms call for full payment by Day 30.

Aging schedules cannot be constructed from the type of summary data reported in financial statements; rather, they must be developed from the firm's accounts receivable ledger. However, well-run firms have computerized accounts receivable records, so it is easy to determine the age of each invoice, to sort electronically by age categories, and thus to generate an aging schedule.

Management should constantly monitor both the DSO and the aging schedule to detect any trends, to see how the firm's collections experience compares with its credit terms, and to see how effectively the credit department is operating in comparison with other firms in the industry. If the DSO starts to lengthen or the aging schedule begins to show an increasing percentage of past-due accounts, then the credit manager should examine why these changes are occurring.

Although increases in the DSO and the aging schedule are warning signs, this does not necessarily indicate the firm's credit policy has weakened. If a firm experiences sharp

TABLE 16-1
Aging Schedules

	Super Set		Wonder Vision	
Age of Account (Days)	Value of Account	Percentage of Total Value	Value of Account	Percentage of Total Value
0–10	$1,344,000	70%	$ 902,400	47%
11–30	576,000	30	499,200	26
31–45	0	0	288,000	15
46–60	0	0	192,000	10
Over 60	0	0	38,400	2
Total receivables	$1,920,000	100%	$1,920,000	100%

seasonal variations or if it is growing rapidly, then both the aging schedule and the DSO may be distorted. To see this point, recall that the DSO is calculated as follows:

$$\text{DSO} = \frac{\text{Accounts receivable}}{\text{Annual sales}/365}$$

Receivables at any point in time reflect sales in the past 1 or 2 months, but sales as shown in the denominator are for the past 12 months. Therefore, a seasonal increase in sales will increase the numerator more than the denominator and hence will raise the DSO, even if customers continue to pay just as quickly as before. Similar problems arise with the aging schedule. If sales are rising, then the percentage in the 0–10-day category will be high; the reverse will occur if sales are falling. Therefore, a change in either the DSO or the aging schedule should be taken as a signal to investigate further; it is not necessarily a sign that customers have changed their payment behaviors.

SELF-TEST

Explain how a new firm's receivables balance is built up over time.

Define days sales outstanding (DSO). What can be learned from it? How is it affected by sales fluctuations?

What is an aging schedule? What can be learned from it? How is it affected by sales fluctuations?

A company has annual sales of $730 million. If its DSO is 35, what is its average accounts receivables balance? **($70 million)**

16-6 Accruals and Accounts Payable (Trade Credit)

Recall that net operating working capital is equal to operating current assets minus operating current liabilities. The previous sections discussed the management of operating current assets (cash, inventory, and accounts receivable), and the following sections discuss the two major types of operating current liabilities: accruals and accounts payable.[13]

16-6a Accruals

Firms generally pay employees on a weekly, biweekly, or monthly basis, so the balance sheet will typically show some accrued wages. Similarly, the firm's own estimated income taxes, employment and income taxes withheld from employees, and sales taxes collected are generally paid on a weekly, monthly, or quarterly basis. Therefore, the balance sheet will typically show some accrued taxes along with accrued wages.

These **accruals** can be thought of as short-term, interest-free loans from employees and taxing authorities, and they increase automatically (that is, *spontaneously*) as a firm's operations expand. However, a firm cannot ordinarily control its accruals: The timing of wage payments is set by economic forces and industry norms, and tax payment dates are established by law. Thus, firms generally use all the accruals they can, but they have little control over the levels of these accounts.

[13]For more on accounts payable management, see James A. Gentry and Jesus M. De La Garza, "Monitoring Accounts Payables," *Financial Review*, November 1990, pp. 559–576.

16-6b Accounts Payable (Trade Credit)

Firms generally make purchases from other firms on credit, recording the unpaid amount as an *account payable*. Accounts payable, or **trade credit**, is the largest single operating current liability, representing about 40% of the current liabilities for an average nonfinancial corporation. The percentage is somewhat larger for smaller firms: Because small companies often have difficulty obtaining financing from other sources, they rely especially heavily on trade credit.

Trade credit is a spontaneous source of financing in the sense that it arises from ordinary business transactions. For example, suppose a firm makes average purchases of $2,000 a day on terms of net 30, meaning that it must pay for goods 30 days after the invoice date. On average, it will owe 30 times $2,000, or $60,000, to its suppliers. If its sales, and consequently its purchases, were to double, then its accounts payable would also double, to $120,000. So simply by growing, the firm would spontaneously generate an additional $60,000 of financing. Similarly, if the terms under which the firm buys were extended from 30 to 40 days, then its accounts payable would expand from $60,000 to $80,000 even with no growth in sales. Thus, both expanding sales and lengthening the credit period generate additional amounts of financing via trade credit.

16-6c The Cost of Trade Credit

Suppose that Microchip Electronics sells on terms of 2/10, net 30. The "true price" of Microchip's products is the net price, or 0.98 times the list price, because any customer can purchase an item at that price as long as payment is made within 10 days. Now consider Personal Computer Company (PCC), which buys its memory chips from Microchip. One chip is listed at $100, so its "true" price to PCC is $98. Now if PCC wants an additional 20 days of credit beyond the 10-day discount period, it must incur a finance charge of $2 per chip for that credit. Thus, the $100 list price consists of two components:

$$\text{List price} = \$98 \text{ true price} + \$2 \text{ finance charge}$$

A Wag of the Finger or Tip of the Hat? *The Colbert Report* and Small Business Payment Terms

On February 17, 2011, *The Colbert Report* featured an interview with Jeffrey Leonard. During a spirited exchange with Stephen Colbert, Leonard accused many large businesses of imposing onerous payment terms on their small suppliers. According to Leonard, when Cisco Systems sells to the U.S. government, Cisco receives its payment in 30 days, the standard credit terms used by the federal government. Yet Cisco changed its own credit policy in 2010 to "net 60," meaning that Cisco's suppliers don't get paid for 60 days. In other words, many small companies essentially are helping Cisco finance its working capital, even though Cisco has over $39 billion in cash. Cisco isn't alone in delaying its payments: Dell, Walmart, and AB InBev (the owner of Anheuser-Busch) also pay slower than 30 days.

Colbert and Leonard agreed on the facts but interpreted them differently. Leonard suggested that the government should help small businesses by requiring its own supplier companies to offer their vendors the same terms as the government does. Colbert, however, suggested (perhaps with tongue-in-cheek) that this was just the natural result of free markets and that no government interference was warranted.

You be the judge. When big companies legally take what they can from smaller companies, should they receive a wag of the finger or a tip of the hat?

The question PCC must ask before it turns down the discount to obtain the additional 20 days of credit is this: Could credit be obtained at a lower cost from a bank or some other lender? To answer this, we compare the total annual cost of financing with the total credit provided by financing, as shown next.

If PCC takes the credit, it must pay a finance charge equal to the $2 discount it is forgoing for each unit it purchases. PCC buys 73,000 of these chips per year, so its total annual financing cost is $146,000: $\$2(73{,}000) = \$146{,}000$.

To determine the net amount of credit gained by forgoing the discount, we need to compare the level of accounts payable that results if PCC takes the credit versus the level if PCC takes the discount. We begin by calculating the number of units purchased daily, which is $73{,}000/365 = 200$. IF PCC takes the discount, its daily purchases are equal to daily units multiplied by the true price: $200(\$98) = \$19{,}600$. By taking the discount, PCC will have 10 days until it must make the payment. The accounts payable balance will equal the product of daily purchases and the number of days until payment: $\$19{,}600(10) = \$196{,}000$. This is called **free trade credit** because the purchaser pays the true price (not the list price that includes the financing charge) but still gets to delay payment until the end of the discount period.

What level of accounts receivable will PCC have if it takes credit and pays in 30 days? PCC's daily purchases don't change, but it now has 30 days until it must pay.[14] The accounts payable balance will equal the product of daily purchases and the number of days until payment: $\$19{,}600(30) = \$588{,}000$.

If PCC takes credit and forgoes the discount, its accounts payable will increase from $196,000 to $588,000, a gain of $392,000: $\$588{,}000 - 196{,}000 = \$392{,}000$. This additional $392,000 is called **costly trade credit** because it has a cost: PCC must pay a finance charge equal to the 2% discount it is forgoing.

The previous results show that if PCC takes the credit, it will receive an additional $392,000 in credit but will pay an additional $146,000 in finance charges. This is equivalent to borrowing at a nominal annual interest rate of 37.2%:

$$\text{Nominal annual costs} = \frac{\$146{,}000}{\$392{,}000} = 37.2\%$$

If PCC can borrow from its bank (or some other source) at an interest rate less than 37.2%, then it should take the 2% discount and forgo the additional trade credit.

PCC's example illustrates the logic, but we can calculate the nominal cost (on an annual basis) of not taking discounts directly from the credit terms. Using PCC's terms (2/10, net 30), the nominal cost is:

$$\begin{aligned}\text{Nominal cost of trade credit} &= \text{Cost per period} \times \text{Number of periods per year} \\ &= \frac{\text{Discount percentage}}{100 - \text{Discount percentage}} \times \frac{365}{\text{Days credit is outstanding} - \text{Discount period}}\end{aligned} \tag{16-6}$$

[14] A question arises here: Should accounts payable reflect gross purchases or purchases net of discounts? Generally accepted accounting principles permit either treatment if the difference is not material, but if the discount is material, then the transaction must be recorded net of discounts, or at "true" prices. Then, the higher payment that results from not taking discounts is reported as an expense called "discounts lost." Therefore, *we show accounts payable net of discounts even if the company does not expect to take discounts.*

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Using PCC's terms (2/10, net 30), the nominal cost is:

$$\text{Nominal cost of trade credit} = \frac{2}{100-2} \times \frac{365}{30-10}$$
$$= 2.04\% \times 18.25 = 37.2\%$$

The trade credit costs PCC 2.04% per period. With 18.25 periods per year, the nominal cost is quite high. However, this nominal annual cost does not consider the compounding of interest. In terms of effective annual interest, the cost of trade credit is even higher:

$$\text{Effective annual rate} = (1.0204)^{18.25} - 1.0 = 1.4459 - 1.0 = 44.6\%$$

Thus, the 37.2% nominal cost calculated with Equation 16-6 actually understates the true cost.

Note, however, that the calculated cost of trade credit can be reduced by paying late. Thus, if PCC could get away with paying in 60 days rather than the specified 30 days, then the effective credit period would become $60 - 10 = 50$ days, the number of times the discount would be lost would fall to $365/50 = 7.3$, and the nominal cost would drop from 37.2% to $2.04\% \times 7.3 = 14.9\%$. Then the effective annual rate would drop from 44.6% to 15.9%:

$$\text{Effective annual rate} = (1.0204)^{7.3} - 1.0 = 1.1589 - 1.0 = 15.9\%$$

In periods of excess capacity, firms may be able to get away with deliberately paying late, or **stretching accounts payable**. However, they will also suffer a variety of problems associated with being a "slow payer." These problems are discussed later in the chapter.

The costs of the additional trade credit from forgoing discounts under some other purchase terms are taken from the chapter's *Excel* ***Tool Kit*** model and shown here as Figure 16-5. As these numbers indicate, the cost of not taking discounts can be substantial.

On the basis of the preceding discussion, trade credit can be divided into two components: (1) **free trade credit**, which involves credit received during the discount period, and (2) **costly trade credit**, which involves credit in excess of the free trade credit and whose cost is an implicit one based on the forgone discounts. *Firms should always use the free component, but they should use the costly component only after analyzing the cost of this capital to make sure it is less than the cost of funds that could be obtained from other sources*. Under the terms of trade found in most industries, the costly component is relatively expensive, so stronger firms generally avoid using it.

FIGURE 16-5
Varying Credit Terms and Their Associated Costs

	A	B	C	D	E	F
287	Days in Year: 365					
288		Discount	Discount	Net	Cost of Additional Credit	
289	Credit Terms	Percentage	Period	Period	Nominal	Effective
290	1/10, net 20	1%	10	20	36.87%	44.32%
291	1/10, net 30	1%	10	30	18.43%	20.13%
292	1/10, net 90	1%	10	90	4.61%	4.69%
293	2/10, net 20	2%	10	20	74.49%	109.05%
294	2/10, net 30	2%	10	30	37.24%	44.59%
295	3/15, net 45	3%	15	45	37.63%	44.86%

Note, though, that firms sometimes offer favorable credit terms in order to stimulate sales. For example, suppose a firm has been selling on terms of 2/10, net 30, with a nominal cost of 37.24%, but a recession has reduced sales and the firm now has excess capacity. It wants to boost the sales of its product without cutting the list price, so it might offer terms of 1/10, net 90, which implies a nominal cost of additional credit of only 4.61%. In this situation, its customers would probably be wise to take the additional credit and reduce their reliance on banks and other lenders. So, turning down discounts is not always a bad decision.

SELF-TEST

What are accruals? How much control do managers have over accruals?

What is trade credit?

What's the difference between free trade credit and costly trade credit?

How does the cost of costly trade credit generally compare with the cost of short-term bank loans?

A company buys on terms of 2/12, net 28. What is its nominal cost of trade credit? **(46.6%)**
The effective cost? **(58.5%)**

16-7 The Cash Budget

Firms must forecast their cash flows. If they are likely to need additional cash, then they should line up funds well in advance. Yet, if they are likely to generate surplus cash, then they should plan for its productive use. The primary forecasting tool is the **cash budget**, illustrated in Figure 16-6, which is based on the chapter's *Excel* ***Tool Kit*** model. The illustrative company is Educational Products Corporation (EPC), which supplies educational materials to schools and retailers in the Midwest. Sales are cyclical, peaking in September and then declining for the balance of the year.

16-7a Monthly Cash Budgets

Cash budgets can be of any length, but EPC and most companies use a monthly cash budget such as the one in Figure 16-6, but set up for 12 months. We used only 6 months for the purpose of illustration. The monthly budget is used for longer-range planning, but a daily cash budget is also prepared at the start of each month to provide a more precise picture of the daily cash flows for use in scheduling actual payments on a day-by-day basis.

The cash budget focuses on cash flows, but it also includes information on forecasted sales, credit policy, and inventory management. Because the statement is a forecast and not a report on historical results, actual results could vary from the figures given. Therefore, the cash budget is generally set up as an expected, or base-case, forecast, but it is created with a model that makes it easy to generate alternative forecasts to see what would happen under different conditions.

Figure 16-6 begins with Panel A, a forecast of gross sales for each month. The next row in Panel A shows possible percentage deviations from the forecasted sales. Because we are showing the base-case forecast, no adjustments are made, but the model is set up to show the effects if sales increase or decrease and so result in "adjusted sales" that are above or below the forecasted levels.

The company sells on terms of "2/10, net 60." This means that a 2% discount is given if payment is made within 10 days; otherwise, the full amount is due in 60 days. However, like most companies, EPC finds that some customers pay late. Experience shows that 20% of customers pay during the month of the sale and take the discount. Another 70% pay

FIGURE 16-6
EPC's Cash Budget, July–December 2017 (Millions of Dollars)

	A	B	C	D	E	F	G	H	I	J	K	L	M	N
371	Scenario: Base Case					May	June	July	August	Sept	Oct	Nov	Dec	Jan
372	Panel A: Forecasted gross sales (manual inputs)					$200	$250	$300	$400	$500	$350	$250	$200	$200
373	Adjustment: % deviation from forecast					0%	0%	0%	0%	0%	0%	0%	0%	0%
374	Adjusted gross sales forecast					$200	$250	$300	$400	$500	$350	$250	$200	$200
375	Panel B: Collections on sales													
376	During sales' month:	0.2	(Sales)(1 – Discount %)					$58.8	$78.4	$98.0	$68.6	$49.0	$39.2	
377	During 2nd month:	0.7	(Prior month's sales)					$175.0	$210.0	$280.0	$350.0	$245.0	$175.0	
378	Due in 3rd month:	0.1	(Sales 2 months ago)					$20.0	$25.0	$30.0	$40.0	$50.0	$35.0	
379	Less bad debts (BD% × Sales 2 months ago)							$0.0	$0.0	$0.0	$0.0	$0.0	$0.0	
380	Total collections							$253.8	$313.4	$408.0	$458.6	$344.0	$249.2	
381	Panel C: Purchases: 60% of next month's sales						$180.0	$240.0	$300.0	$210.0	$150.0	$120.0	$120.0	
382	Panel D: Payments													
383	Pmt for last month's purchases (30 days of credit)							$180.0	$240.0	$300.0	$210.0	$150.0	$120.0	
384	Wages and salaries							$30.0	$40.0	$50.0	$40.0	$30.0	$30.0	
385	Lease payments							$30.0	$30.0	$30.0	$30.0	$30.0	$30.0	
386	Other payments (interest on LT bonds, dividends, etc.)							$30.0	$30.0	$30.0	$30.0	$30.0	$30.0	
387	Taxes									$30.0			$30.0	
388	Payment for plant construction									$150.0				
389	Total payments							$270.0	$340.0	$590.0	$310.0	$240.0	$240.0	
390	Panel E: Net cash flows													
391	Assumed excess cash on hand at start of forecast period							$0.0						
392	Net cash flow (NCF): Total collections – Total payments							$16.2	$26.6	$182.0	$148.6	$104.0	$9.2	
393	Cumulative NCF: Prior month cum plus this month's NCF							$16.2	$42.8	$224.8	$76.2	$27.8	$37.0	
394	Panel F: Net cash position before financing or investing													
395	Target cash balance							$10.0	$10.0	$10.0	$10.0	$10.0	$10.0	
396	Surplus cash or loan needed: Cum NCF – Target cash							$26.2	$52.8	$234.8	$86.2	$17.8	$27.0	
397	Panel G: Maximum loan requirements and investible funds													
398	Max required loan (most negative on Row 396)						$234.8							
399	Max investable funds (most positive on Row 396)						$27.0							

Source: See the file ***Ch16 Tool Kit.xlsx***. Numbers are reported as rounded values for clarity, but are calculated using *Excel*'s full precision. Thus, intermediate calculations using the figure's rounded values will be inexact.

Notes:

1. Although the budget period is July through December, sales and purchases data for May and June are needed to determine collections and payments during July and August.
2. Firms can both borrow and pay off commercial loans on a daily basis, so the $26.2 million loan needed for July would likely be gradually borrowed as needed on a daily basis, and during October the $234.8 million loan that presumably existed at the beginning of the month would be reduced daily to the $86.2 million ending balance—which, in turn, would be completely paid off sometime during November.
3. The data in the figure are for EPC's base-case forecast. Data for alternative scenarios are shown in the chapter's *Excel* ***Tool Kit*** model.

during the month immediately following the sale, and 10% are late, paying in the second month after the sale.[15] Panel B shows the collections on sales based on these assumed collection rates.

[15]Because we are using a monthly forecast instead of a daily forecast, we assume that all purchases are made on the first day of the month. Thus, discounted payments are received in the month of the sale, regular payments are received in the month after the sale, and late payments are received two months after the sale. Obviously, a daily budget would be more accurate. Also, a negligible percentage of sales results in bad debts. The low bad-debt losses evident here result from EPC's careful screening of customers and its generally tight credit policies. However, the cash budget model is able to show the effects of bad debts, so EPC's CFO could show top management how cash flows would be affected if the firm relaxed its credit policy in order to stimulate sales or if the recession worsened and more customers were forced to delay payments.

Panel C shows forecasted materials purchases, which equal 60% of the following month's sales. EPC buys on terms of net 30, meaning that it receives no discounts and is required to pay for its purchases within 30 days of the purchase date.

Panel D shows forecasted payments for materials purchases (from Panel C), labor, leases, other payments such as dividends and interest on long-term bonds, taxes (due in September and December), and a payment of $150 million in September for enlarging an existing manufacturing facility.

Panel E shows the monthly net cash flows due to the differences between total forecasted payments (from Panel D) and total forecasted collections (from Panel B). Panel E also shows the cumulative monthly net cash flow, including any excess cash on hand at the start of the forecast (which we assume was zero). This cumulative cash flow is the amount of cash the firm would have on hand at the end of the month if it neither borrowed nor invested.

Panel F begins with EPC's target cash balance of $10 million each month. (We explain how companies choose target cash balances later in the chapter.) Subtracting the monthly target cash balances from Panel E's cumulative monthly cash flows provides the monthly *loan requirements or surplus cash available for investment*, as shown in the last row of Panel F. A negative number indicates the need for a loan, whereas a positive number indicates surplus cash that is available for investment or other uses.

Looking back at the last row in Panel E, the cumulative net cash flow is $37 million in by December. Because this number is positive, it indicates that EPC's cumulative cash flow is positive. However, Panel G shows that EPC will need to borrow up to $234.8 million at some point in the forecast. If EPC does not conduct a cash budget forecast, EPC might not be able to arrange financing to cover the months of negative cash flow. In particular, EPC needs a line of credit (LOC) that allows it to begin borrowing in July (see the last row in Panel F) and then continue drawing on the LOC through September. Then, when its cash flows turn positive in October, it would start repaying the LOC and completely pay it off sometime in November. Although the forecast is on a monthly basis, EPC would draw and then pay down the LOC on a daily basis.[16]

Under the base-case forecast, the CFO will need to arrange a line of credit so that the firm can borrow up to $234.8 million, increasing the loan over time as funds are needed and repaying it later when cash flows become positive. The treasurer would show the cash budget to the bankers when negotiating for the line of credit. Lenders would want to know how much the firm expects to need, when the funds will be needed, and when the loan will be repaid. The lenders—and EPC's top executives—would question the treasurer about the budget, and they would want to know how the forecasts would be affected if sales were higher or lower than those projected, how changes in customers' payment times would affect the forecasts, and the like. The focus would be on these two questions: *How accurate is the forecast likely to be? What would be the effects of significant errors?* The first question could best be answered by examining historical forecasts, and the second by running different scenarios as we do in the *Excel* ***Tool Kit*** model.

resource

See ***Ch16 Tool Kit.xlsx*** *on the textbook's Web site for details.*

No matter how hard we try, no forecast will ever be exactly correct, and this includes cash budgets. You can imagine the bank's reaction if the company negotiated a loan of $235 million and then came back a few months later saying that it had underestimated its requirements and needed to boost the loan to, say, $260 million. The banker might refuse, thinking the company was not managed very well. Therefore, EPC's treasurer would undoubtedly want to build a cushion into the line of credit—say, a maximum

[16]Note that EPC's cash budget ignores interest paid on the LOC and interest earned on positive cash balances. Because the loans will be outstanding for a relatively short period, the impact of neglecting interest payments is small. However, interest expenses and income could be incorporated by adding rows and following steps similar to those used in Chapter 12 to forecast financial statements.

commitment of $260 million rather than the forecasted requirement of $234.8 million. However, as we discuss later in the chapter, banks charge commitment fees for guaranteed lines of credit; thus, the higher the cushion built into the line of credit, the more costly the credit will be. This is another reason why it is important to develop accurate forecasts.

16-7b Cash Budgets versus Income Statements and Free Cash Flows

If you look at the cash budget, it looks similar to an income statement. However, the two statements are quite different. Here are four key differences: (1) In an income statement, the focus would be on sales, not collections. (2) An income statement would show accrued taxes, wages, and so forth—not the actual payments. (3) An income statement would show depreciation as an expense, but it would not show expenditures on new fixed assets. (4) An income statement would show a cost for goods purchased when those goods were sold, not for when they were ordered or paid.

These are obviously large differences, so it would be a big mistake to confuse a cash budget with an income statement. Also, the cash flows shown on the cash budget are different from the firm's free cash flows, because FCF reflects after-tax operating income and the investments required to maintain future operations whereas the cash budget reflects only the actual cash inflows and outflows during a particular period.

The bottom line is that cash budgets, income statements, and free cash flows are all important and are related to one another, but they are also quite different. Each is designed for a specific purpose, and the main purpose of the cash budget is to forecast the firm's liquidity position, not its profitability.

16-7c Daily Cash Budgets

Note that if cash inflows and outflows do not occur uniformly during each month, then the actual funds needed might be quite different from the indicated amounts. The data in Figure 16-6 show the situation on the last day of each month, and we see that the maximum projected loan during the forecast period is $234.8 million. Yet if all payments had to be made on the 1st of the month but most collections came on the 30th, then EPC would have to make $270 million of payments in July before it received the $253.8 million from collections. In that case, the firm would need to borrow about $270 million in July, not the $26.2 million shown in Figure 16-6. This would make the bank unhappy—perhaps so unhappy that it would not extend the requested credit. A daily cash budget would have revealed this situation.

resource

*See **Ch16 Tool Kit.xlsx** on the textbook's Web site for details.*

Figure 16-6 was prepared using *Excel,* which makes it easy to change the assumptions. In the ***Tool Kit*** model, we examine the cash flow effects of changes in sales, in customers' payment patterns, and so forth. Also, the effects of changes in credit policy and inventory management could be examined through the cash budget.

SELF-TEST

How could the cash budget be used when negotiating the terms of a bank loan?

How would a shift from a tight credit policy to a relaxed policy be likely to affect a firm's cash budget?

How would the cash budget be affected if our firm's suppliers offered us terms of "2/10, net 30," rather than "net 30," and we decided to take the discount?

Suppose a firm's cash flows do not occur uniformly throughout the month. What effect would this have on the accuracy of the forecasted borrowing requirements based on a monthly cash budget? How could the firm deal with this problem?

16-8 Cash Management and the Target Cash Balance

Companies need cash to pay for expenses related to daily ongoing operations, including labor, raw materials, utility bills, and taxes. Companies also need cash for several other predictable purposes, including major purchases and payments to investors (interest payments, principal payments, and dividend payments). Following are the issues that companies consider when deciding how much cash to hold in support of ongoing operations, which is called the **target cash balance**. We discuss major purchases and payments to investors in Section 16-10.

16-8a Routine (but Uncertain) Operating Transactions

Cash balances are necessary in business operations. Payments must be made in cash, and receipts are deposited in the cash account. Cash balances associated with routine payments and collections are known as **transactions balances**. Cash inflows and outflows are unpredictable, and the degree of predictability varies among firms and industries. Therefore, firms need to hold some cash to meet random, unforeseen fluctuations in inflows and outflows. These "safety stocks" are called **precautionary balances**, and the less predictable the firm's cash flows, the larger such balances should be. Research confirms this and shows that companies with volatile cash flows do in fact hold higher cash balances.[17]

In addition to holding cash for transactions and precautionary reasons, it is essential that the firm have sufficient cash to take trade discounts. Suppliers frequently offer customers discounts for early payment of bills. As shown previously, the cost of not taking discounts is sometimes very high, so firms should have enough cash to permit payment of bills in time to take advantage of discounts.

Many companies have a line of credit to cover unexpected cash needs; we discuss lines of credit in Section 16-12.

16-8b Compensating Balances

A bank makes money by lending out funds that have been deposited with it, so the larger its deposits, the better the bank's profit position. If a bank is providing services to a customer, then it may require that customer to leave a minimum balance on deposit to help offset the costs of providing those services. Also, banks may require borrowers to hold their transactions deposits at the bank. Both types of deposits are called **compensating balances**. In a 1979 survey, 84.7% of responding companies reported they were required to maintain compensating balances to help pay for bank services; only 13.3% reported paying direct fees for banking services.[18] By 1996, those findings were reversed: Only 28% paid for bank services with compensating balances, while 83% paid direct fees.[19]

Use It or Lose *Part of* It: Cash Can Be Costly!

Suppose you had to pay a fee for the cash you carry in your pockets and wallet. Sound crazy to you? If you were a larger corporation instead of a person, this could soon become common. To see why, take a look at the path from a company's profits to a country's central bank.

As we write this in 2015, many companies have recovered from the Great Recession of 2007 and have had strong earnings for several years. However, some are holding much of this profit as cash instead of using it to fund new business growth or shareholder distributions. This hesitance to use the cash could be because they don't believe they have enough profitable investment opportunities or because they are worried about another credit crisis similar to 2007. In addition, some companies, such as Apple, have earned large profits overseas that will be subject to additional taxes if sent back the United States. Rather than pay the tax, companies with international profits often have large cash deposits at global banks. The net effect is that corporate cash holdings are at record highs.

Companies deposit cash at banks, which normally hold only part in reserve and invest the rest in loans to other customers or in financial securities. However, many banks are choosing instead to have large deposits at their country's central bank. This lack of investment could be because banks are reluctant to make as many risky loans as they did prior to 2007 or because interest rates on financial securities are very low.

Central banks typically pay interest on deposits made by member banks. However, the European Central Bank (ECB) began charging its member banks a fee in 2014 for deposits with the ECB—the ECB isn't paying interest on deposits; it is in effect charging interest! Not surprisingly, many global banks are beginning to pass these costs along by charging their own corporate customers a fee for large deposit accounts.

How will companies and banks respond? Will they invest more in new projects, distribute more to investors, or let their cash accounts slowly erode due to fees? Only time will tell.

The use of compensating balances to pay for services has declined, but some companies hold additional cash in such accounts because they believe these balances improve relationships with their banks. However, this applies primarily to small banks and small companies. See the box "Use It or Lose *Part of* It: Cash Can Be Costly!" for the situation faced by large companies.

SELF-TEST

Why is cash management important?

What are the primary motives for holding cash?

16-9 Cash Management Techniques

In terms of dollar volume, most business is conducted by large firms, many of which operate nationally or globally. They collect cash from many sources and make payments from a number of different cities or even countries. For example, companies such as IBM, General Electric, and Hewlett-Packard have manufacturing plants all around the world, even more sales offices, and bank accounts in virtually every city in which they do business. Their collection centers follow sales patterns. However, while some disbursements are made from local offices, most are made in the cities where manufacturing occurs or from the home office. Thus, a major corporation might have hundreds or even thousands of bank accounts located in cities all over the globe, but there is no reason to think that inflows and outflows will balance in each account. Therefore, a system must be in place to transfer funds from where

they come in to where they are needed, to arrange loans to cover net corporate shortfalls, and to invest net corporate surpluses without delay.[20]

Before describing specific cash management techniques, we begin with a brief overview of payment, clearing, and settlement systems.

16-9a Payment, Clearing, and Settlement Systems[21]

When you make a small, simple, cash deposit in person at your bank, your account balance is increased immediately to show the deposit.[22] However, most financial transactions are not conducted with cash, so a payment infrastructure system is required to enable adjustments to the bank accounts of payers and payees.[23]

For nonfinancial companies and individuals, most payment paths begin with the payer's bank account and end at the payee's account. The primary forms of payment, in terms of total dollar value transactions, are: (1) direct transfers from account to account, (2) paper checks, (3) credit cards, and (4) debit cards.[24] Following is a brief description of each method.

Two automated clearing house (ACH) network operators, the Federal Reserve and The Clearing House, facilitate direct transfers on behalf of users from one bank account to another. For example, many companies make direct deposits to employees' bank accounts for payroll and make direct deposits to suppliers' bank accounts for purchases. Individuals often pre-authorize regular payments from their bank accounts, such as monthly cell phone bills and mortgage payments. In addition, an online purchase can be made by a one-time authorization to deduct funds from the purchaser's bank account. Direct transfers are often called **wire transfers**.

Even with an ACH transaction, the actual funds in the bank accounts don't change immediately due to the following reasons. First, most banks batch ACH orders several times a day rather submitting each order in real time. Second, after processing ACH orders, a payer's bank puts a hold on the pending amount coming from the payer's account and verifies that the payer has sufficient funds; also, the payee's bank puts a pending credit on the payee's account. Third, **clearing** occurs when the ACH network confirms that the banks themselves have sufficient funds and transmits the confirmation to the banks.[25] Fourth, **settlement** occurs when the payer's bank actually deducts the payment amount from the account balance and the payee's bank actually deposits the

[20]For more information on cash management, see Bruce J. Summers, "Clearing and Payment Systems: The Role of the Central Bank," *Federal Reserve Bulletin*, February 1991, pp. 81–91.

[21]The Bank for International Settlements (BIS) and the Committee on Payment and Settlement Systems (CPSS) periodically publish descriptions of payment systems used by many large countries. For more details on the United States payments system, see the BIS/CPSS publication *Payment, Clearing and Settlement Systems in the CPSS Countries,* 2012, Vol. 2, pp. 471–508. It is available at the BIS Web site: **www.bis.org.**

[22]Most banks will allow you to withdraw your cash deposit later that same day, but this is not required! Instead, a bank is allowed to wait until the next business day before you can access those funds for cash withdrawals or even for settling debit card charges. In fact, the bank can wait until the second business day if you didn't make the deposit in person. For more, see the Consumer Financial Protection Bureau at **www.consumerfinance.gov/askcfpb/1029/i-made-cash-deposit-my-checking-account-i-attempted-withdrawal-later-day-and-was-told-i-could-not-withdraw-until-tomorrow-can-bank-do.html.**

[23]We use the term "bank" here to denote all deposit transaction accounts that allow payments, whether they are at a commercial bank, S&L, or other financial intermediary.

[24]See pages 485–486 in the source cited in footnote 21. These rankings are based on 2010 data. Based on trends, it is likely that debit card transactions will exceed those of credit cards by the time you read this.

[25]The Federal Reserve Board and The Clearing House operate special transfer systems for banks to make large payments on behalf of themselves or their customers.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

amount into the payee's account. The complete process can happen within minutes or it can take 1 to 2 business days, depending on the complexity of the transaction.

Printed checks still make up a very large percentage of payments. The Check 21 Act, implemented in 2004, allows banks to exchange digital images of checks rather than the actual pieces of paper. Digital checks may be cleared directly between the payer's and payee's bank, through the Federal Reserve, or through services provided by third-party banks or clearing houses. Before Check 21, clearing could take 2 to 5 days, but now most checks clear in a single day. Keep in mind that clearing and settlement are not the same—clearing is the exchange of information, but funds can't be spent until settlement, which can take another business day or two.

When you use your debit or credit card to make a purchase, the information goes from the purchasing location (which can be face-to-face or online) to the seller's bank, then to the payment card network (such as MasterCard of Visa), and then to the bank that issued your card. If your card's bank approves, you have just made a purchase. However, cash doesn't move instantaneously from your bank account to the seller's bank account, even with most debit card purchases.[26] Similar to the ACH process, orders are batched, holds are placed, and time can lapse before interbank clearing by the payment card network occurs. The payment card network will clear the transaction, but it is up to the banks to settle the transactions.

Because payments don't occur instantaneously, companies must maintain a sufficient balance in their bank accounts to handle the transactions.[27] The following sections describe different techniques that companies use.

16-9b Synchronizing Cash Flow

If you as an individual were to receive income once a year, then you would probably put it in the bank, draw down your account periodically, and have an average balance for the year equal to about half of your annual income. If instead you received income weekly and paid rent, tuition, and other charges on a daily basis, then your average bank balance would still be about half of your periodic receipts and thus only 1/52 as large as if you received income only once annually.

Exactly the same situation holds for businesses: By timing their cash receipts to coincide with their cash outlays, firms can hold their transactions balances to a minimum. Recognizing this fact, firms such as utilities, oil companies, and credit card companies arrange to bill customers—and to pay their own bills—on regular "billing cycles" throughout the month. This **synchronization of cash flows** provides cash when it is needed and thus enables firms to reduce their average cash balances.

16-9c Using Float

Float is defined as the difference between the balance shown in a firm's (or individual's) checkbook and the balance on the bank's records. Suppose a firm writes and mails, on average, checks in the amount of $5,000 each day, and suppose it takes 6 days for these checks to clear and be deducted from the firm's bank account. This will cause the firm's own checkbook to show a balance that is $30,000 smaller than the balance on the bank's

[26]Some debit card transaction clear and settle at the time of the purchase, but most don't. For more details, see Susan Herbst-Murphy, "Clearing and Settlement of Interbank Card Transactions: A MasterCard Tutorial for Federal Reserve Payments Analysts." This paper is available at the Federal Reserve Bank of Philadelphia: **https://www.philadelphiafed.org/-/media/consumer-credit-and-payments/payment-cards-center/publications/discussion-papers/2013/d-2013-october-clearing-settlement.pdf?la=en.**

[27]Banks will offer "overdraft" protection, but it is costly.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. records; this difference is called **disbursement float**. Now suppose the firm also receives checks in the amount of $5,000 daily but that it loses 4 days while those checks are being deposited and cleared. This will result in $20,000 of **collections float**. The firm's **net float** is the difference between the $30,000 positive disbursement float and the $20,000 negative collections float, which will be $10,000. In sum, collections float is bad, disbursement float is good, and positive net float is even better.

Delays that cause float will occur because it takes time for checks to: (1) travel through the mail (mail float), (2) be processed by the receiving firm (processing float), and (3) clear through the banking system (clearing, or availability, float). Basically, the size of a firm's net float is a function of its ability to speed up collections on checks it receives and to slow down collections on checks it writes. Efficient firms go to great lengths to speed up the processing of incoming checks, thus putting the funds to work faster, and they try to stretch their own payments out as long as possible, sometimes by disbursing checks from banks in remote locations.

16-9d Speeding Up Collections

Two major techniques are used to speed collections and to get funds where they are needed: lockboxes and electronic transfers.

LOCKBOXES

A **lockbox system** is one of the oldest cash management tools. In a lockbox system, incoming checks are sent to post office boxes rather than to the firm's corporate headquarters. For example, a firm headquartered in New York City might have its West Coast customers send their payments to a post office box in San Francisco, its customers in the Southwest send their checks to Dallas, and so on, rather than having all checks sent to New York City. Several times a day, a local bank will empty the lockbox and deposit the checks into the company's local account. The bank then provides the firm with a daily record of the receipts collected, usually via an electronic data transmission system in a format that permits online updating of the firm's accounts receivable records.

A lockbox system reduces the time required to receive incoming checks, to deposit them, and to get them cleared through the banking system. Lockbox services can make funds available as many as 2 to 5 days faster than for checks mailed directly to a company.

ELECTRONIC PAYMENTS

Firms are increasingly demanding payments of larger bills by automatic electronic transfers instead of printed checks. As described in previous sections, clearing and settlement can occur much more quickly with electronic payments.

SELF-TEST

What are some methods firms can use to accelerate receipts?

16-10 Managing Short-Term Investments

Short-term investments include short-term financial assets such as U.S. Treasury securities, U.S. agency securities, certificates of deposits, time deposits, and commercial paper. There are three reasons companies hold short-term investments: (1) for liquidation just prior to scheduled transactions, (2) for unexpected opportunities, and (3) to reduce the company's risk.

Your Check Isn't in the Mail

Issuing payroll checks to thousands of employees is expensive—in both the time and resources it takes the company to print, process, and deliver the checks, and in the time it takes the employee to deposit or cash the check. Paper checks cost a company between $1 and $2 each. Multiply that by thousands of employees, some of whom are paid weekly or biweekly, and it adds up to a lot of money every year. Direct deposit of payroll checks into the employee's checking account reduces these costs, but there are still many employees, especially seasonal, temporary, part-time, or young employees, who don't have a checking account.

A growing solution to high check costs and the needs of these "unbanked" employees is the payroll debit card. Companies, in partnership with a bank, issue the employee a debit card that is automatically filled each payday. The employee either uses the debit card to make purchases or withdraws cash at an ATM. The cost to load a debit card is around $0.20, and so saves the companies 80%–90% of the cost to print a check, and saves the unbanked employee from paying the frequently usurious check-cashing fees that can be 10% or more per week. In fact, because debit card transactions that are processed as a credit card result in fees to the merchant, there is a small amount of money available to provide a rebate to the employer. For example, Premier Pay Cards offers a 0.1% rebate to the employer on certain purchases the employee makes with the debit card.

Although payroll debit cards may be good for companies, they aren't always as good for employees as advertised. *The New York Times* reported that high ATM transaction fees, balance inquiry fees, inactivity fees, and overdraft protection fees can eat up $40 per month in fees—even more than the frequently usurious fees charged by check-cashing services. These high fees help banks offer those attractive rebates to the employers, with the employees essentially paying their employers for the privilege of being paid.

Sources: "The End of the Paycheck," *Fortune Small Business Magazine*, December 5, 2006; "Paid via Card, Workers Feel Sting of Fees," *The New York Times,* June 30, 2013; and **www.premierpaycards.com.**

Some future transaction dates and amounts are known with a high degree of certainty. For example, a company knows the dates on which it will need cash to make interest, principal, and dividend payments; if a company has decided to make a major purchase, such as a new machine or even a new factory, the company knows the dates on which it will pay for the purchase. A company's payment isn't complete until the funds have been deducted from the company's bank account and credited to the depositor's bank account. Because a company doesn't actually need a balance in the bank account until the payment is deducted, most companies try to keep their bank account balances (which pay zero or very low interest rates) as low as possible until the day the payment is deducted. For example, if a company has a scheduled dividend payment, the company is likely to hold the amount needed for the payment in the form of short-term investments such as T-bills or other interest-paying short-term securities. The company will liquidate these short-term investments and deposit the proceeds into its bank accounts just prior to the required payment date.

Short-term investments that are designated for making scheduled payments, such as those just described, are temporary in the sense that a company acquires these short-term investments and plans to hold them for a specific period and for a particular use. The following sections describe short-term investments that are less transitory.

Some companies hold short-term investments even though they haven't planned a specific use for them and even though the rate of return on short-term investments is very low. For example, some companies compete in businesses that have growth opportunities that arise unexpectedly. If such a company doesn't have stable cash flows or ready access to credit markets (perhaps because the company is small or doesn't have a high credit rating), it might not be able to take advantage of an unexpected opportunity. Therefore, the company might hold short-term investments, which are **speculative balances** in the sense that the company speculates that it will have an opportunity to use them and

subsequently earn much more than the rate on short-term investments. Studies show that such firms do hold relatively high levels of marketable securities. In contrast, cash holdings are less important to large firms with high credit ratings, because they have quick and inexpensive access to capital markets. As expected, such firms hold relatively low levels of cash.[28]

Holding short-term investments reduces a company's risk of facing a liquidity crisis, such as the ones that occurred during the economic downturn and credit crunch of the 2007 recession. A stockpile of short-term investments also reduces transaction costs due to issuing securities because the investments can be liquidated instead.

Although there are good reasons many companies hold short-term investments, there are too many companies holding too much cash. As we write this in early 2015, U.S. nonfinancial companies hold about $2.48 trillion in cash, making up about 2% of their total assets. Some companies, such as Apple and Microsoft, have much larger cash-to-assets ratios. Even with the uncertain economic environment, it is hard to believe that investors would not benefit by cash distributions instead of cash stockpiles.

SELF-TEST

Why might a company hold low-yielding marketable securities when it could earn a much higher return on operating assets?

16-11 Short-Term Financing

The three possible short-term financing policies described earlier in the chapter were distinguished by the relative amounts of short-term debt used under each policy. The aggressive policy called for the greatest use of short-term debt, and the conservative policy called for using the least; maturity matching fell in between. Although short-term credit is generally riskier than long-term credit, using short-term funds does have some significant advantages. The pros and cons of short-term financing are considered in this section.

16-11a Advantages of Short-Term Financing

First, a short-term loan can be obtained much faster than long-term credit. Lenders will insist on a more thorough financial examination before extending long-term credit, and the loan agreement will have to be spelled out in considerable detail. Therefore, if funds are needed in a hurry, the firm should look to the short-term markets.

Second, if its needs for funds are seasonal or cyclical, then a firm may not want to commit itself to long-term debt. There are three reasons for this: (1) Flotation costs are higher for long-term debt than for short-term credit. (2) Although long-term debt can be repaid early (provided the loan agreement includes a prepayment provision), prepayment penalties can be expensive. Accordingly, if a firm thinks its need for funds will diminish in the near future, it should choose short-term debt. (3) Long-term loan agreements always contain provisions, or covenants, that constrain the firm's future actions. Short-term credit agreements are generally less restrictive.

The third advantage is that, because the yield curve is normally upward sloping, interest rates are generally lower on short-term debt. Thus, under normal conditions, interest costs at the time the funds are obtained will be lower if the firm borrows on a short-term rather than a long-term basis.

[28]See the study by Opler, Pinkowitz, Stulz, and Williamson cited in footnote 17.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

16-11b Disadvantages of Short-Term Debt

Even though short-term rates are often lower than long-term rates, using short-term credit is riskier for two reasons: (1) If a firm borrows on a long-term basis, then its interest costs will be relatively stable over time, but if it uses short-term credit, then its interest expense will fluctuate widely, at times going quite high. For example, the rate banks charged large corporations for short-term debt more than tripled over a 2-year period in the 1980s, rising from 6.25% to 21%. Many firms that had borrowed heavily on a short-term basis simply could not meet their rising interest costs; as a result, bankruptcies hit record levels during that period. (2) If a firm borrows heavily on a short-term basis, a temporary recession may render it unable to repay this debt. If the borrower is in a weak financial position, then the lender may not extend the loan, which could force the firm into bankruptcy.

SELF-TEST

What are the advantages and disadvantages of short-term debt compared with long-term debt?

16-12 Short-Term Bank Loans

Loans from commercial banks generally appear on balance sheets as notes payable. A bank's importance is actually greater than it appears from the dollar amounts shown on balance sheets because banks provide *nonspontaneous* funds. As a firm's financing needs increase, it requests additional funds from its bank. If the request is denied, the firm may be forced to abandon attractive growth opportunities. The key features of bank loans are discussed in the following paragraphs.

16-12a Maturity

Although banks do make longer-term loans, *the bulk of their lending is on a short-term basis*—about two-thirds of all bank loans mature in a year or less. Bank loans to businesses are frequently written as 90-day notes, so the loan must be repaid or renewed at the end of 90 days. Of course, if a borrower's financial position has deteriorated, then the bank may refuse to renew the loan. This can mean serious trouble for the borrower.

16-12b Promissory Notes

When a bank loan is approved, the agreement is executed by signing a **promissory note**. The note specifies: (1) the amount borrowed, (2) the interest rate, (3) the repayment schedule, which can call for either a lump sum or a series of installments, (4) any collateral that might have to be put up as security for the loan, and (5) any other terms and conditions to which the bank and the borrower have agreed. When the note is signed, the bank credits the borrower's checking account with the funds; hence, both cash and notes payable increase on the borrower's balance sheet.

16-12c Compensating Balances

Banks sometimes require borrowers to maintain an average demand deposit (checking account) balance of 10% to 20% of the loan's face amount. This is called a compensating balance, and such balances raise the effective interest rate on the loans. For example, if a firm needs $80,000 to pay off outstanding obligations but it must maintain a 20% compensating balance, then it must borrow $100,000 to obtain a usable $80,000. If the

stated annual interest rate is 8%, the effective cost is actually 10%: $8,000 interest divided by $80,000 of usable funds equals 10%.[29]

As we noted earlier in the chapter, recent surveys indicate that compensating balances are much less common now than earlier. In fact, compensating balances are now illegal in many states. Despite this trend, some small banks in states where compensating balances are legal still require their customers to maintain them.

16-12d Informal Line of Credit

A **line of credit** is an informal agreement between a bank and a borrower indicating the maximum credit the bank will extend to the borrower. For example, on December 31, a bank loan officer might indicate to a financial manager that the bank regards the firm as being "good" for up to $80,000 during the forthcoming year, provided the borrower's financial condition does not deteriorate. If on January 10 the financial manager signs a 90-day promissory note for $15,000, this would be called "taking down" $15,000 of the total line of credit. This amount would be credited to the firm's checking account at the bank, and the firm could borrow additional amounts up to a total of $80,000 outstanding at any one time.

16-12e Revolving Credit Agreement

A **revolving credit agreement** is a formal line of credit often used by large firms. To illustrate, suppose in 2016 Texas Petroleum Company negotiated a revolving credit agreement for $100 million with a group of banks. The banks were formally committed for 4 years to lend the firm up to $100 million if the funds were needed. Texas Petroleum, in turn, paid an annual **commitment fee** of 0.25% on the unused balance of the commitment to compensate the banks for making the commitment. Thus, if Texas Petroleum did not take down any of the $100 million commitment during a year, it would still be required to pay a $250,000 annual fee, normally in monthly installments of $20,833.33. If it borrowed $50 million on the first day of the agreement, then the unused portion of the line of credit would fall to $50 million and the annual fee would fall to $125,000. Of course, interest would also have to be paid on the money Texas Petroleum actually borrowed. As a general rule, the interest rate on "revolvers" is pegged to the London Interbank Offered Rate (LIBOR), the T-bill rate, or some other market rate, so the cost of the loan varies over time as interest rates change. The interest that Texas Petroleum must pay was set at the prime lending rate plus 1.0%.

Observe that a revolving credit agreement is similar to an informal line of credit but has an important difference: The bank has a *legal obligation* to honor a revolving credit agreement, and it receives a commitment fee. Neither the legal obligation nor the fee exists under the informal line of credit.

Often a line of credit will have a **cleanup clause** that requires the borrower to reduce the loan balance to zero at least once a year. Keep in mind that a line of credit typically is designed to help finance seasonal or cyclical peaks in operations, not as a source of permanent capital. For example, our cash budget for Educational Products Corporation showed negative flows from July through September but positive flows from October through December. Also, the cumulative net cash flow goes positive in November, indicating that the firm could pay off its loan at that time. If the cumulative flows were always negative, this would indicate that the firm was using its credit lines as a permanent source of financing.

[29]Note, however, that the compensating balance may be set as a minimum monthly *average,* and if the firm would maintain this average anyway, then the compensating balance requirement would not raise the effective interest rate. Also, note that these loan compensating balances are *added to* any compensating balances that the firm's bank may require for services performed, such as clearing checks.

16-12f Costs of Bank Loans

The costs of bank loans vary for different types of borrowers at any given point in time and for all borrowers over time. Interest rates are higher for riskier borrowers, and rates are also higher on smaller loans because of the fixed costs involved in making and servicing loans. A bank publishes its **prime rate**, which is defined as the rate a bank charges its strongest customers, and then scales this rate up for other customers. For example, a small company might get a loan with a rate of "prime plus 1.0%." Despite the prime rate's definition, many bank loans to very large, strong customers are made at rates tied to LIBOR (such as "LIBOR plus 1.5%"), with a net cost often below prime the prime rate:

Rates on March 9, 2015	
Prime	3.25%
1-Year LIBOR	0.69%

Bank rates vary widely over time depending on economic conditions and Federal Reserve policy. When the economy is weak, loan demand is usually slack, inflation is low, and the Fed makes plenty of money available to the system. As a result, rates on all types of loans are relatively low. Conversely, when the economy is booming, loan demand is typically strong, the Fed restricts the money supply to fight inflation, and the result is high interest rates. As an indication of the kinds of fluctuations that can occur, the prime rate during 1980 rose from 11% to 21% in just 4 months; during 1994, it rose from 6% to 9%.

CALCULATING BANKS' INTEREST CHARGES: REGULAR (OR "SIMPLE") INTEREST

Banks calculate interest in several different ways. In this section, we explain the procedure used for most business loans. For illustration purposes, we assume a loan of $10,000 at 5.25%, with a 365-day year. Interest must be paid monthly, and the principal is payable "on demand" if and when the bank wants to end the loan. Such a loan is called a **regular interest** loan or a **simple interest** loan.

We begin by dividing the nominal interest rate by 365 to obtain the rate per day. This rate is expressed as a *decimal fraction*, not as a percentage:

$$\text{Simple interest rate per day} = \frac{\text{Nominal rate}}{\text{Days in year}} = 0.0525/365 = 0.0001438356$$

The monthly interest payment is the product of the daily rate, the number of days in the month, and the loan amount. The average month has 30.4167 days $(365/12 = 30.4167)$, so we will use this value to determine the average monthly payment, although the bank would use the actual number of days in each month. The average monthly interest charge is $43.75:

$$\begin{aligned}\text{Interest charge for month} &= (\text{Rate per day})(\text{Amount of loan})(\text{Days in month}) \\ &= (0.0001438356)(\$10{,}000)(30.4167) = \$43.75\end{aligned}$$

The *effective interest rate* on a loan depends on how frequently interest must be paid—the more frequently interest is paid, the higher the effective rate. If interest is paid once per year, then the nominal rate is also the effective rate. However, if interest must be paid monthly, then the effective rate is $(1 + 0.0525/12)^{12} - 1 = 5.378\%$.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

CALCULATING BANKS' INTEREST CHARGES: ADD-ON INTEREST

Some lenders sometimes use **add-on interest**. They begin by calculating the total amount of interest that must be repaid. For car loans, this total is often the total interest that would be paid on an amortizing loan, as described in Chapter 4. But some lenders calculate the total interest as the product of the loan's annual interest rate, the number of years until the loan is fully repaid, and the amount that is borrowed. Notice that this second approach ignores the fact that some principal will be repaid with each payment, making the total interest charge much higher than that of an amortizing loan.

It is called *add-on interest* because the total interest charged by the lender is added to the amount borrowed to determine the total amount of payments. This total of interest and principal is divided by the number of payments to get the amount of each equal payment.[30]

To illustrate, suppose you borrow $10,000 on an add-on basis at a nominal rate of 7.25%, with the loan to be repaid in 12 monthly installments. At a 7.25% add-on rate, the total interest payments are $\$725 = (0.0725)(1 \text{ year})(\$10{,}000)$. The total amount of interest and principal is $\$10{,}725 = \$725 + \$10{,}000$, and the monthly payment is $\$893.75 = \$10{,}725/12$.

To find the annual percentage rate (APR), we use *Excel*'s **RATE** function or a financial calculator: N = 12, PV = 10000, PMT = −893.75, and FV = 0. With these inputs, the monthly rate is 1.093585%. Multiply the monthly rate by 12 to get 13.12%, which is the APR that a lender would report to the borrower. This is quite a bit above the 7.25% rate, and the effective rate on an add-on loan is even higher. The effective annual rate is $(1.010936)^{12} - 1 = 13.94\%$, which is even higher. As this example shows, add-on interest loans can be very costly for borrowers.

SELF-TEST

What is a promissory note, and what are some terms that are normally included in promissory notes?

What is a line of credit? A revolving credit agreement?

What's the difference between simple interest and add-on interest?

Explain how a firm that expects to need funds during the coming year might make sure that the needed funds will be available.

How does the cost of costly trade credit generally compare with the cost of short-term bank loans?

If a firm borrowed $500,000 at a rate of 10% simple interest with monthly interest payments and a 365-day year, what would be the required interest payment for a 30-day month? **($4,109.59)** *If interest must be paid monthly, what would be the effective annual rate?* **(10.47%)**

If this loan had been made on a 10% add-on basis, payable in 12 end-of-month installments, what would be the monthly payment amount? **($45,833.33)** *What is the annual percentage rate?* **(17.97%)** *The effective annual rate?* **(19.53%)**

[30]Each payment consists of interest and principal, but the relative amounts are not always calculated like those for an amortizing loan. Instead, many lenders use other methods that often result in higher interest and lower principal in the early life of the loans. Of course, lower principal payments in the early periods of repayments mean that more principal will be owed relative to an amortizing loan if the borrower repays the loan early. One such method is the **Rule of 78**, which allocates interest in the following manner. First, determine the sum of the payment numbers. For example, with 12 payments, the sum of 1 through 12 is 78; with 24 payments, the sum is 300. Second, divide the number of remaining payments (not including the current payment) by the previously calculated total sum to determine the portion of the payment that goes to interest. For example, if 12 payments remain on a 12-month loan, divide 12 by 78 to get 0.1538 = 12/78. For this first month, 15.38% of the payment would be for interest and the remainder would be principal.

16-13 Commercial Paper

WWW

For updates on the outstanding balances of commercial paper, go to **www.federalreserve.gov/econresdata/releases/statisticsdata.htm** *and check out the volume statistics for Commercial Paper and the weekly releases for Assets and Liabilities of Commercial Banks in the United States.*

Commercial paper is a type of unsecured promissory note issued by large, strong firms and sold primarily to other business firms, to insurance companies, to pension funds, to money market mutual funds, and to banks. In March 2015, there was approximately $1.2 trillion of commercial paper outstanding, versus nearly $1.8 trillion of commercial and industrial bank loans. Most, but not all, commercial paper outstanding is issued by financial institutions.

16-13a Maturity and Cost

Maturities of commercial paper generally vary from 1 day to 9 months, with an average of about 5 months.[31] The interest rate on commercial paper fluctuates with supply and demand conditions—it is determined in the marketplace, varying daily as conditions change. Recently, commercial paper rates have ranged from 1.5 to 3.5 percentage points below the stated prime rate and up to half of a percentage point above the T-bill rate. For example, in March 2015, the average rate on 3-month commercial paper was 0.10%, the prime rate was 3.25%, and the 3-month T-bill rate was 0.03%.

WWW

For current rates, see **www.federalreserve.gov/econresdata/releases/statisticsdata.htm** *and look at the Daily Releases for Selected Interest Rates.*

16-13b Use of Commercial Paper

The use of commercial paper is restricted to a comparatively small number of very large companies that are exceptionally good credit risks. Dealers prefer to handle the paper of firms whose net worth is $100 million or more and whose annual borrowing exceeds $10 million. One potential problem with commercial paper is that a debtor who has a temporary financial difficulty may receive little help because commercial paper dealings are generally less personal than are bank relationships. Thus, banks are generally more able and willing to help a good customer weather a temporary storm than is a commercial paper dealer. On the other hand, using commercial paper permits a corporation to tap a wide range of credit sources, including financial institutions outside its own area and industrial corporations across the country; this can reduce interest costs.

SELF-TEST

What is commercial paper?

What types of companies can use commercial paper to meet their short-term financing needs?

How does the cost of commercial paper compare with the cost of short-term bank loans? With the cost of Treasury bills?

16-14 Use of Security in Short-Term Financing

Thus far, we have not addressed the question of whether or not short-term loans should be secured. Commercial paper is never secured, but other types of loans can be on a **secured basis** with collateral if this is deemed necessary or desirable. Other things held constant, it is better to borrow on an unsecured basis because the bookkeeping and monitoring activities for secured loans can be onerous. However, firms often find that they can borrow only if they put up some type of collateral to protect the lender or that, by using security, they can borrow at a much lower rate.

[31]The maximum maturity without SEC registration is 270 days. Also, commercial paper can be sold only to "sophisticated" investors; otherwise, SEC registration would be required even for maturities of 270 days or less.

Companies can employ several different kinds of collateral, including marketable stocks or bonds, land or buildings, equipment, inventory, and accounts receivable. Marketable securities make excellent collateral, but few firms that need loans also hold portfolios of stocks and bonds. Similarly, real property (land and buildings) and equipment are good forms of collateral, but they are generally used as security for long-term loans rather than for working capital loans. Therefore, most secured short-term business borrowing involves the use of accounts receivable and inventories as collateral.

resource

*For a more detailed discussion of secured financing, see **Web Extension 16A** on the textbook's Web site.*

Consider the case of a Chicago hardware dealer who requested a $200,000 bank loan to modernize and expand his store. After examining the business' financial statements, his bank indicated that it would lend him a maximum of $100,000 and that the effective interest rate would be 9%. The owner had a substantial personal portfolio of stocks, and he offered to put up $300,000 of high-quality stocks to support the $200,000 loan. The bank then granted the full $200,000 loan at the prime rate of 3.25%. The store owner might also have used his inventories or receivables as security for the loan, but processing costs would have been high.[32]

SELF-TEST

What is a secured loan?

What are some types of current assets that are pledged as security for short-term loans?

SUMMARY

This chapter discussed working capital management and short-term financing. The key concepts covered are listed below.

- **Working capital** refers to current assets used in operations, and **net working capital** is defined as current assets minus all current liabilities. **Net operating working capital** is defined as operating current assets minus operating current liabilities.
- Under a **relaxed policy** for current assets, a firm would hold relatively large amounts of each type of current asset. Under a **restricted policy**, the firm would hold minimal amounts of these items.
- **Permanent operating current assets** are the operating current assets the firm holds even during slack times, whereas **temporary operating current assets** are the additional operating current assets needed during seasonal or cyclical peaks. The methods used to finance permanent and temporary operating current assets define the firm's **operating current assets financing policy**.
- A **maturity matching** approach to short-term financing involves matching, to the extent possible, the maturities of assets and liabilities, so that temporary operating current assets are financed with short-term debt and permanent operating current assets and fixed assets are financed with long-term debt or equity. Under an **aggressive** approach, some permanent operating current assets, and perhaps even some fixed assets, are financed with short-term debt. A **conservative** approach would be to use

[32]The term "asset-based financing" is often used as a synonym for "secured financing." In recent years, accounts receivable have been used as security for long-term bonds, permitting corporations to borrow from lenders such as pension funds rather than just from banks and other traditional short-term lenders.

long-term sources to finance all permanent operating capital and some of the temporary operating current assets.

- The **inventory conversion period** is the average time required to convert materials into finished goods and then to sell those goods:

$$\text{Inventory conversion period} = \text{Inventory} \div \text{Cost of goods sold per day}$$

- The **average collection period** is the average length of time required to convert the firm's receivables into cash—that is, to collect cash following a sale:

$$\text{Average collection period} = \text{DSO} = \text{Receivables} \div (\text{Sales}/365)$$

- The **payables deferral period** is the average length of time between the purchase of materials and labor and the payment of cash for them:

$$\text{Payables deferral period} = \text{Payables} \div \text{Cost of goods sold per day}$$

- The **cash conversion cycle (CCC)** is the length of time between the firm's actual cash expenditures to pay for productive resources (materials and labor) and its own cash receipts from the sale of products (that is, the length of time between paying for labor and materials and collecting on receivables):

$$\begin{array}{c} \text{Cash} \\ \text{conversion} \\ \text{cycle} \end{array} = \begin{array}{c} \text{Inventory} \\ \text{conversion} \\ \text{period} \end{array} + \begin{array}{c} \text{Average} \\ \text{collection} \\ \text{period} \end{array} - \begin{array}{c} \text{Payables} \\ \text{deferral} \\ \text{period} \end{array}$$

- A **cash budget** is a schedule showing projected cash inflows and outflows over some period. The cash budget is used to predict cash surpluses and deficits, and it is the primary cash management planning tool.
- The *primary goal of cash management* is to minimize the amount of cash the firm must hold for conducting its normal business activities while at the same time maintaining a sufficient cash reserve to take discounts, pay bills promptly, and meet any unexpected cash needs.
- The **transactions balance** is the cash necessary to conduct routine day-to-day business; **precautionary balances** are cash reserves held to meet random, unforeseen needs. A **compensating balance** is a minimum checking account balance that a bank requires as compensation either for services provided or as part of a loan agreement.
- The twin goals of *inventory management* are: (1) to ensure that the inventories needed to sustain operations are available, but (2) to hold the costs of ordering and carrying inventories to the lowest possible level.
- When a firm sells goods to a customer on credit, an **account receivable** is created.
- A firm can use an **aging schedule** and the **days sales outstanding (DSO)** to monitor its receivables balance and to help avoid an increase in bad debts.
- A firm's **credit policy** consists of four elements: (1) credit period, (2) discounts given for early payment, (3) credit standards, and (4) collection policy.
- **Accounts payable**, or **trade credit**, arises spontaneously as a result of credit purchases. Firms should use all the **free trade credit** they can obtain, but they should use **costly trade credit** only if it is less expensive than other forms of short-term debt. Suppliers often offer discounts to customers who pay within a stated period. The following

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. equation may be used to calculate the nominal cost, on an annual basis, of not taking such discounts:

$$\text{Nominal annual cost of trade credit} = \frac{\text{Discount percentage}}{100 - \text{Discount percentage}} \times \frac{365}{\text{Days credit is outstanding} - \text{Discount period}}$$

- The advantages of short-term credit are: (1) the *speed* with which short-term loans can be arranged, (2) increased *flexibility,* and (3) generally *lower interest rates* than with long-term credit. The principal disadvantage of short-term credit is the *extra risk* the borrower must bear because: (1) The lender can demand payment on short notice. (2) The cost of the loan will increase if interest rates rise.
- Bank loans are an important source of short-term credit. When a bank loan is approved, a **promissory note** is signed. It specifies: (1) the amount borrowed, (2) the percentage interest rate, (3) the repayment schedule, (4) the collateral, and (5) any other conditions to which the parties have agreed.
- **Speculative balances** are short-term, highly liquid financial assets held by a company in excess of the amounts needed to support operating activities or to cover expected near-term payments.
- A **line of credit** is an informal agreement between the bank and the borrower indicating the maximum amount of credit the bank will extend to the borrower.
- A **revolving credit agreement** is a formal line of credit often used by large firms; it involves a **commitment fee**.
- A **simple interest** loan is one in which interest must be paid monthly and the principal is payable "on demand" if and when the bank wants to end the loan.
- An **add-on interest loan** is one in which interest is calculated and added to the funds received to determine the face amount of the installment loan.
- **Commercial paper** is unsecured short-term debt issued by large, financially strong corporations. Although the cost of commercial paper is lower than the cost of bank loans, it can be used only by large firms with exceptionally strong credit ratings.
- Sometimes a borrower will find it is necessary to borrow on a **secured basis**, in which case the borrower pledges assets such as real estate, securities, equipment, inventories, or accounts receivable as collateral for the loan. For a more detailed discussion of secured financing, see ***Web Extension 16A.***

QUESTIONS

(16-1) Define each of the following terms:

a. Working capital; net working capital; net operating working capital
b. Current asset usage policies: relaxed policy, restricted policy, and moderate policy
c. Permanent operating current assets; temporary operating current assets
d. Current asset financing policies: maturity matching, aggressive, and conservative
e. Inventory conversion period; average collection period; payables deferral period; cash conversion cycle
f. Cash budget; target cash balance
g. Transactions balances; compensating balances; precautionary balances
h. Trade (cash) discounts

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

i. Credit policy; credit period; credit standards; collection policy; cash discounts
j. Account receivable; days sales outstanding; aging schedule
k. Accruals; trade credit
l. Stretching accounts payable; free trade credit; costly trade credit
m. Promissory note; line of credit; revolving credit agreement
n. Commercial paper; secured loan

(16-2) What are the two principal reasons for holding cash? Can a firm estimate its target cash balance by summing the cash held to satisfy each of the two reasons?

(16-3) Is it true that, when one firm sells to another on credit, the seller records the transaction as an account receivable while the buyer records it as an account payable and that, disregarding discounts, the receivable typically exceeds the payable by the amount of profit on the sale?

(16-4) What are the four elements of a firm's credit policy? To what extent can firms set their own credit policies as opposed to accepting policies that are dictated by its competitors?

(16-5) What are the advantages of matching the maturities of assets and liabilities? What are the disadvantages?

(16-6) From the standpoint of the borrower, is long-term or short-term credit riskier? Explain. Would it ever make sense to borrow on a short-term basis if short-term rates were above long-term rates?

(16-7) Discuss this statement: "Firms can control their accruals within fairly wide limits."

(16-8) Is it true that most firms are able to obtain some free trade credit and that additional trade credit is often available, but at a cost? Explain.

(16-9) What kinds of firms use commercial paper?

SELF-TEST PROBLEMS

Solutions Shown in Appendix A

(ST-1) Working Capital Policy

The Calgary Company is attempting to establish a current assets policy. Fixed assets are $600,000, and the firm plans to maintain a 50% debt-to-assets ratio. Calgary has no operating current liabilities. The interest rate is 10% on all debt. Three alternative current asset policies are under consideration: 40%, 50%, and 60% of projected sales. The company expects to earn 15% before interest and taxes on sales of $3 million. Calgary's effective federal-plus-state tax rate is 40%. What is the expected return on equity under each asset policy?

(ST-2) Current Asset Financing

Vanderheiden Press Inc. and the Herrenhouse Publishing Company had the following balance sheets as of December 31, 2016 (thousands of dollars):

	Vanderheiden Press	Herrenhouse Publishing
Current assets	$100,000	$ 80,000
Fixed assets (net)	100,000	120,000
Total assets	$200,000	$200,000
Short-term debt	$ 20,000	$ 80,000
Long-term debt	80,000	20,000
Common stock	50,000	50,000
Retained earnings	50,000	50,000
Total liabilities and equity	$200,000	$200,000

Earnings before interest and taxes for both firms are $30 million, and the effective federal-plus-state tax rate is 40%.

a. What is the return on equity for each firm if the interest rate on short-term debt is 10% and the rate on long-term debt is 13%?
b. Assume that the short-term rate rises to 20%, that the rate on new long-term debt rises to 16%, and that the rate on existing long-term debt remains unchanged. What would be the return on equity for Vanderheiden Press and Herrenhouse Publishing under these conditions?
c. Which company is in a riskier position? Why?

PROBLEMS

Answers Are in Appendix B

EASY PROBLEMS 1–5

(16-1) Inventory Management

Williams & Sons last year reported sales of $12 million, cost of goods sold (COGS) of $10 million, and an inventory turnover ratio of 2. The company is now adopting a new inventory system. If the new system is able to reduce the firm's inventory level and increase the firm's inventory turnover ratio to 5 while maintaining the same level of sales and COGS, how much cash will be freed up?

(16-2) Receivables Investment

Medwig Corporation has a DSO of 17 days. The company averages $3,500 in sales each day (all customers take credit). What is the company's average accounts receivable?

(16-3) Cost of Trade Credit

What are the nominal and effective costs of trade credit under the credit terms of 3/15, net 30?

(16-4) Cost of Trade Credit

A large retailer obtains merchandise under the credit terms of 1/15, net 45, but routinely takes 60 days to pay its bills. (Because the retailer is an important customer, suppliers allow the firm to stretch its credit terms.) What is the retailer's effective cost of trade credit?

(16-5) Accounts Payable

A chain of appliance stores, APP Corporation, purchases inventory with a net price of $500,000 each day. The company purchases the inventory under the credit terms of 2/15, net 40. APP always takes the discount but takes the full 15 days to pay its bills. What is the average accounts payable for APP?

INTERMEDIATE PROBLEMS 6–12

(16-6) Receivables Investment

Snider Industries sells on terms of 2/10, net 45. Total sales for the year are $1,500,000. Thirty percent of customers pay on the 10th day and take discounts; the other 70% pay, on average, 50 days after their purchases.

a. What is the days sales outstanding?
b. What is the average amount of receivables?
c. What would happen to average receivables if Snider toughened its collection policy with the result that all nondiscount customers paid on the 45th day?

(16-7) Cost of Trade Credit

Calculate the nominal annual cost of nonfree trade credit under each of the following terms. Assume that payment is made either on the discount date or on the due date.

a. 1/10, net 20
b. 2/10, net 60

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

c. 3/10, net 45
d. 2/10, net 45
e. 2/10, net 40

(16-8) Cost of Trade Credit

(a) If a firm buys under terms of 3/15, net 45, but actually pays on the 20th day and *still takes the discount,* what is the nominal cost of its nonfree trade credit?
(b) Does it receive more or less credit than it would if it paid within 15 days?

(16-9) Cost of Trade Credit

Grunewald Industries sells on terms of 2/10, net 40. Gross sales last year were $4,562,500 and accounts receivable averaged $437,500. Half of Grunewald's customers paid on the 10th day and took discounts. What are the nominal and effective costs of trade credit to Grunewald's nondiscount customers? (*Hint:* Calculate daily sales based on a 365-day year, calculate the average receivables for discount customers, and then find the DSO for the nondiscount customers.)

(16-10) Effective Cost of Trade Credit

The D.J. Masson Corporation needs to raise $500,000 for 1 year to supply working capital to a new store. Masson buys from its suppliers on terms of 3/10, net 90, and it currently pays on the 10th day and takes discounts. However, it could forgo the discounts, pay on the 90th day, and thereby obtain the needed $500,000 in the form of costly trade credit. What is the effective annual interest rate of this trade credit?

(16-11) Cash Conversion Cycle

Negus Enterprises has an inventory conversion period of 50 days, an average collection period of 35 days, and a payables deferral period of 25 days. Assume that cost of goods sold is 80% of sales.

a. What is the length of the firm's cash conversion cycle?
b. If annual sales are $4,380,000 and all sales are on credit, what is the firm's investment in accounts receivable?
c. How many times per year does Negus Enterprises turn over its inventory?

(16-12) Working Capital Cash Flow Cycle

Strickler Technology is considering changes in its working capital policies to improve its cash flow cycle. Strickler's sales last year were $3,250,000 (all on credit), and its net profit margin was 7%. Its inventory turnover was 6.0 times during the year, and its DSO was 41 days. Its annual cost of goods sold was $1,800,000. The firm had fixed assets totaling $535,000. Strickler's payables deferral period is 45 days.

a. Calculate Strickler's cash conversion cycle.
b. Assuming Strickler holds negligible amounts of cash and marketable securities, calculate its total assets turnover and ROA.
c. Suppose Strickler's managers believe the annual inventory turnover can be raised to 9 times without affecting sale or profit margins. What would Strickler's cash conversion cycle, total assets turnover, and ROA have been if the inventory turnover had been 9 for the year?

CHALLENGING PROBLEMS 13–17

(16-13) Current Asset Usage Policy

Payne Products had $1.6 million in sales revenues in the most recent year and expects sales growth to be 25% this year. Payne would like to determine the effect of various current assets policies on its financial performance. Payne has $1 million of fixed assets and intends to keep its debt ratio at its historical level of 60%. Payne's debt interest rate is currently 8%. You are to evaluate three different current asset policies: (1) a restricted

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

policy in which current assets are 45% of projected sales, (2) a moderate policy with 50% of sales tied up in current assets, and (3) a relaxed policy requiring current assets of 60% of sales. Earnings before interest and taxes are expected to be 12% of sales. Payne's tax rate is 40%.

a. What is the expected return on equity under each current asset level?
b. In this problem, we have assumed that the level of expected sales is independent of current asset policy. Is this a valid assumption? Why or why not?
c. How would the overall risk of the firm vary under each policy?

(16-14) Cash Budgeting

Dorothy Koehl recently leased space in the Southside Mall and opened a new business, Koehl's Doll Shop. Business has been good, but Koehl frequently runs out of cash. This has necessitated late payment on certain orders, which is beginning to cause a problem with suppliers. Koehl plans to borrow from the bank to have cash ready as needed, but first she needs a forecast of how much she should borrow. Accordingly, she has asked you to prepare a cash budget for the critical period around Christmas, when needs will be especially high.

Sales are made on a cash basis only. Koehl's purchases must be paid for during the following month. Koehl pays herself a salary of $4,800 per month, and the rent is $2,000 per month. In addition, she must make a tax payment of $12,000 in December. The current cash on hand (on December 1) is $400, but Koehl has agreed to maintain an average bank balance of $6,000—this is her target cash balance. (Disregard the amount in the cash register, which is insignificant because Koehl keeps only a small amount on hand in order to lessen the chances of robbery.)

The estimated sales and purchases for December, January, and February are shown below. Purchases during November amounted to $140,000.

	Sales	Purchases
December	$160,000	$40,000
January	40,000	40,000
February	60,000	40,000

a. Prepare a cash budget for December, January, and February.
b. Suppose that Koehl starts selling on a credit basis on December 1, giving customers 30 days to pay. All customers accept these terms, and all other facts in the problem are unchanged. What would the company's loan requirements be at the end of December in this case? (*Hint:* The calculations required to answer this part are minimal.)

(16-15) Cash Discounts

Suppose a firm makes purchases of $3.65 million per year under terms of 2/10, net 30, and takes discounts.

a. What is the average amount of accounts payable net of discounts? (Assume the $3.65 million of purchases is net of discounts—that is, gross purchases are $3,724,489.80, discounts are $74,489.80, and net purchases are $3.65 million.)
b. Is there a cost of the trade credit the firm uses?
c. If the firm did not take discounts but did pay on the due date, what would be its average payables and the cost of this nonfree trade credit?
d. What would be the firm's cost of not taking discounts if it could stretch its payments to 40 days?

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(16-16) Trade Credit

The Thompson Corporation projects an increase in sales from $1.5 million to $2 million, but it needs an additional $300,000 of current assets to support this expansion. Thompson can finance the expansion by no longer taking discounts, thus increasing accounts payable. Thompson purchases under terms of 2/10, net 30, but it can delay payment for an additional 35 days—paying in 65 days and thus becoming 35 days past due—without a penalty because its suppliers currently have excess capacity. What is the effective, or equivalent, annual cost of the trade credit?

(16-17) Bank Financing

The Raattama Corporation had sales of $3.5 million last year, and it earned a 5% return (after taxes) on sales. Recently, the company has fallen behind in its accounts payable. Although its terms of purchase are net 30 days, its accounts payable represents 60 days' purchases. The company's treasurer is seeking to increase bank borrowing in order to become current in meeting its trade obligations (that is, to have 30 days' payables outstanding). The company's balance sheet is as follows (in thousands of dollars):

Cash	$ 100	Accounts payable	$ 600
Accounts receivable	300	Bank loans	700
Inventory	1,400	Accruals	200
Current assets	$1,800	Current liabilities	$1,500
Land and buildings	600	Mortgage on real estate	700
Equipment	600	Common stock, $0.10 par	300
		Retained earnings	500
Total assets	$3,000	Total liabilities and equity	$3,000

a. How much bank financing is needed to eliminate the past-due accounts payable?
b. Assume that the bank will lend the firm the amount calculated in Part a. The terms of the loan offered are 8%, simple interest, and the bank uses a 360-day year for the interest calculation. What is the interest charge for 1 month? (Assume there are 30 days in a month.)
c. Now ignore Part b and assume that the bank will lend the firm the amount calculated in Part a. The terms of the loan are 7.5%, add-on interest, to be repaid in 12 monthly installments.

   (1) What is the total loan amount?
   (2) What are the monthly installments?
   (3) What is the APR of the loan?
   (4) What is the effective rate of the loan?

d. Would you, as a bank loan officer, make this loan? Why or why not?

SPREADSHEET PROBLEM

(16-18) Build a Model: Cash Budgeting

resource

Start with the partial model in the file ***Ch16 P18 Build a Model.xlsx*** on the textbook's Web site. Rusty Spears, CEO of Rusty's Renovations, a custom building and repair company, is preparing documentation for a line of credit request from his commercial banker. Among the required documents is a detailed sales forecast for parts of 2017 and 2018:

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

	Sales	Labor and Raw Materials
May 2017	$60,000	$75,000
June	100,000	90,000
July	130,000	95,000
August	120,000	70,000
September	100,000	60,000
October	80,000	50,000
November	60,000	20,000
December	40,000	20,000
January 2018	30,000	NA

Estimates obtained from the credit and collection department are as follows: collections within the month of sale, 15%; collections during the month following the sale, 65%; collections the second month following the sale, 20%. Payments for labor and raw materials are typically made during the month following the one in which these costs were incurred. Total costs for labor and raw materials are estimated for each month as shown in the table.

General and administrative salaries will amount to approximately $15,000 a month; lease payments under long-term lease contracts will be $5,000 a month; depreciation charges will be $7,500 a month; miscellaneous expenses will be $2,000 a month; income tax payments of $25,000 will be due in both September and December; and a progress payment of $80,000 on a new office suite must be paid in October. Cash on hand on July 1 will amount to $60,000, and a minimum cash balance of $40,000 will be maintained throughout the cash budget period.

a. Prepare a monthly cash budget for the last 6 months of 2017.
b. Prepare an estimate of the required financing (or excess funds)—that is, the amount of money Rusty's Renovations will need to borrow (or will have available to invest)—for each month during that period.
c. Assume that receipts from sales come in uniformly during the month (i.e., cash receipts come in at the rate of 1/30 each day) but that all outflows are paid on the 5th of the month. Will this have an effect on the cash budget—in other words, would the cash budget you have prepared be valid under these assumptions? If not, what can be done to make a valid estimate of peak financing requirements? No calculations are required, although calculations can be used to illustrate the effects.
d. Rusty's Renovations produces on a seasonal basis, just ahead of sales. Without making any calculations, discuss how the company's current ratio and debt ratio would vary during the year assuming all financial requirements were met by short-term bank loans. Could changes in these ratios affect the firm's ability to obtain bank credit? Why or why not?
e. If its customers began to pay late, this would slow down collections and thus increase the required loan amount. Also, if sales dropped off, this would have an effect on the required loan amount. Perform a sensitivity analysis that shows the effects of these two factors on the maximum loan requirement.

MINI CASE

Karen Johnson, CFO for Raucous Roasters (RR), a specialty coffee manufacturer, is rethinking her company's working capital policy in light of a recent scare she faced when RR's corporate banker, citing a nationwide credit crunch, balked at renewing RR's line of credit. Had the line of credit not been renewed, RR would not have been able to make payroll, potentially forcing the company out of business. Although the line of credit was ultimately renewed, the scare has forced Johnson to examine carefully each component of RR's working capital to make sure it is needed, with the goal of determining whether the line of credit can be eliminated entirely. In addition to (possibly) freeing RR from the need for a line of credit, Johnson is well aware that reducing working capital will improve free cash flow.

Historically, RR has done little to examine working capital, mainly because of poor communication among business functions. In the past, the production manager resisted Johnson's efforts to question his holdings of raw materials, the marketing manager resisted questions about finished goods, the sales staff resisted questions about credit policy (which affects accounts receivable), and the treasurer did not want to talk about the cash and securities balances. However, with the recent credit scare, this resistance has become unacceptable and Johnson has undertaken a company-wide examination of cash, marketable securities, inventory, and accounts receivable levels.

Johnson also knows that decisions about working capital cannot be made in a vacuum. For example, if inventories could be lowered without adversely affecting operations, then less capital would be required, and free cash flow would increase. However, lower raw materials inventories might lead to production slowdowns and higher costs, and lower finished goods inventories might lead to stockouts and loss of sales. So, before inventories are changed, it will be necessary to study operating as well as financial effects. The situation is the same with regard to cash and receivables. Johnson has begun her investigation by collecting the ratios shown here. (The partial cash budget shown after the ratios is used later in this mini case.)

	RR	Industry
Current	1.75	2.25
Quick	0.92	1.16
Total liabilities/assets	58.76%	50.00%
Turnover of cash and securities	16.67	22.22
Days sales outstanding (365-day basis)	45.63	32.00
Inventory turnover	10.80	20.00
Fixed assets turnover	7.75	13.22
Total assets turnover	2.60	3.00
Profit margin on sales	2.07%	3.50%
Return on equity (ROE)	10.45%	21.00%
Payables deferral period	30.00	33.00

	NCFs						
(12)	Cash on hand at start of forecast			$3,000.00			
(13)	NCF: Collections − Payments = Line 5 − Line 11			$13,857.64	$18,311.85		
(14)	Cum NCF: Prior + this mos. NCF			$16,857.64	$35169.49		
	Cash Surplus (or Loan Requirement)						
(15)	Target cash balance			1,500.00	1,500.00		
(16)	Surplus cash or loan needed			$15,357.64	$33,669.49		

a. Johnson plans to use the preceding ratios as the starting point for discussions with RR's operating team. Based on the data, does RR seem to be following a relaxed, moderate, or restricted current asset usage policy?
b. How can one distinguish between a relaxed but rational working capital policy and a situation in which a firm simply has excessive current assets because it is inefficient? Does RR's working capital policy seem appropriate?
c. Calculate the firm's cash conversion cycle given that annual sales are $660,000 and cost of goods sold represents 90% of sales. Assume a 365-day year.
d. Is there any reason to think that RR may be holding too much inventory?
e. If RR reduces its inventory without adversely affecting sales, what effect should this have on free cash flow: (1) in the short run and (2) in the long run?
f. Johnson knows that RR sells on the same credit terms as other firms in its industry. Use the ratios presented earlier to explain whether RR's customers pay more or less

promptly than those of its competitors. If there are differences, does that suggest RR should tighten or loosen its credit policy? What four variables make up a firm's credit policy, and in what direction should each be changed by RR?

g. Does RR face any risks if it tightens its credit policy?
h. If the company reduces its DSO without seriously affecting sales, what effect would this have on free cash flow: (1) in the short run and (2) in the long run?
i. What is the impact of higher levels of accruals, such as accrued wages or accrued taxes? Is it likely that RR could make changes to accruals?
j. Assume that RR purchases $200,000 (net of discounts) of materials on terms of 1/10, net 30, but that it can get away with paying on the 40th day if it chooses not to take discounts. How much free trade credit can the company get from its equipment supplier, how much costly trade credit can it get, and what is the nominal annual interest rate of the costly credit? Should RR take discounts?
k. Cash doesn't earn interest, so why would a company have a positive target cash balance?
l. What might RR do to reduce its target cash balance without harming operations?
m. RR tries to match the maturity of its assets and liabilities. Describe how RR could adopt either a more aggressive or a more conservative financing policy.
n. What are the advantages and disadvantages of using short-term debt as a source of financing?
o. Would it be feasible for RR to finance with commercial paper?
p. In an attempt to better understand RR's cash position, Johnson developed a cash budget for the first 2 months of the year. She has the figures for the other months, but they are not shown. After looking at the cash budget, answer the following questions.

    1. What does the cash budget show regarding the target cash level?
    2. Should depreciation expense be explicitly included in the cash budget? Why or why not?
    3. What are some other potential cash inflows besides collections?
    4. How can interest earned or paid on short-term securities or loans be incorporated in the cash budget?
    5. In her preliminary cash budget, Johnson has assumed that all sales are collected and thus that RR has no bad debts. Is this realistic? If not, how would bad debts be dealt with in a cash budgeting sense? (*Hint:* Bad debts will affect collections but not purchases.)

SELECTED ADDITIONAL CASES

The following cases from CengageCompose cover many of the concepts discussed in this chapter and are available at **http://compose.cengage.com.**

Klein-Brigham Series:
Case 29, "Office Mates, Inc.," which illustrates how changes in current asset policy affect expected profitability and risk; Case 32, "Alpine Wear, Inc.," which illustrates the mechanics of the cash budget and the rationale behind its use; Case 50, "Toy World, Inc.," and Case 66, "Sorenson Stove Company," which deal with cash budgeting; Case 33, "Upscale Toddlers, Inc.," which deals with credit policy changes; and Case 34, "Texas Rose Company," which focuses on receivables management.

Brigham-Buzzard Series:
Case 11, "Powerline Network Corporation (Working Capital Management)."

CHAPTER 17

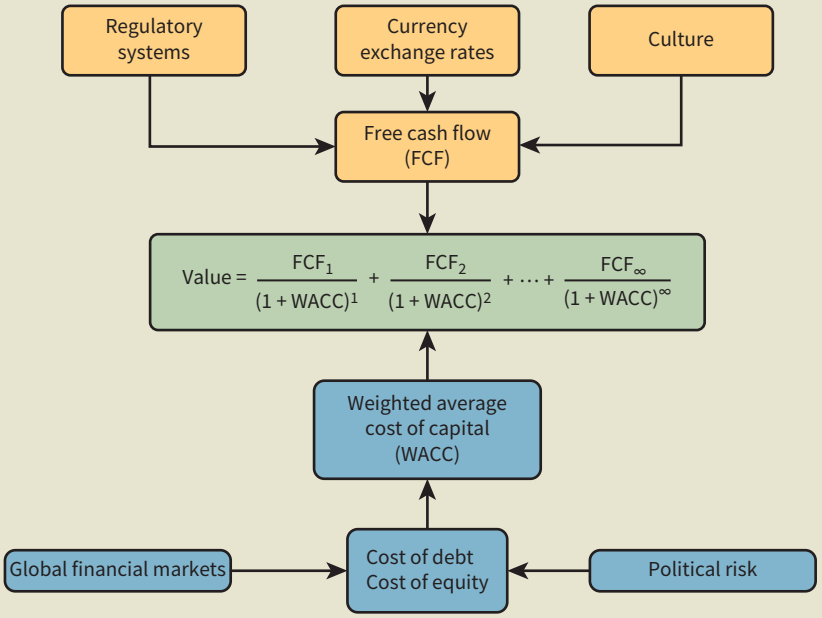
Multinational Financial Management*

In early 2014, Medtronic was a quintessential American success story. Founded in Minnesota by two brothers-in-law, Earl Bakken and Palmer Hermundslie, Medtronic began by repairing electronic medical equipment in a garage. When Mr. Bakken invented a heart pacemaker small enough to run on batteries, the business took off. After a near bankruptcy in the early 1960s, a Minnesota venture capital fund provided cash and financial expertise. Medtronic began its global operations in 1967 and its stock went public on the NYSE in 1977. By 2014, sales were over $17 billion and it had a global presence in over 140 countries.

In early 2015, Medtronic continued to grow by acquiring Covidien, an Irish medical technology company less than half its size. However, the American portion of the success story ends there, because Medtronic reincorporated in Ireland as a part of Covidien and moved its executive headquarters to Dublin.

Why? Part of the reason is due to a more favorable tax code in Ireland than in the United States. Medtronic isn't the only company to follow this strategy, which is called a tax inversion. As we write this in mid-2015, Congress and the president are wrestling with ways to address this issue.

---



*Earlier editions of this chapter benefited from the help of Professor Roy Crum of the University of Florida and Subu Venkataraman of Morgan Stanley.

Corporate Valuation in a Global Context

The intrinsic value of a firm is determined by the size, timing, and risk of its expected future free cash flows (FCF). This is true for foreign as well as domestic operations, but the FCF of a foreign operation is affected by exchange rates, cultural differences, and the host country's regulatory environment. In addition, global financial markets and political risk can affect the cost of capital.

resource

The textbook's Web site contains an Excel *file that will guide you through the chapter's calculations. The file for this chapter is* ***Ch17 Tool Kit.xlsx****, and we encourage you to open the file and follow along as you read the chapter.*

Managers of multinational companies must deal with a wide range of issues that are not present when a company operates in a single country. In this chapter, we highlight the key differences between multinational and domestic corporations, and we discuss the effects these differences have on the financial management of multinational businesses.

17-1 Multinational, or Global, Corporations

The terms **multinational corporations**, **transnational corporations**, **multinational enterprises**, and **global corporations** are used to describe firms that operate in an integrated fashion in a number of countries. Rather than merely buying resources from and selling goods to foreign nations, multinational firms often make direct investments in fully integrated operations, from extraction of raw materials, through the manufacturing process, and to distribution to consumers throughout the world. Today, multinational corporate networks control a large and growing share of the world's technological, marketing, and productive resources.

Companies "go global" for many reasons, including the following:

1. *To broaden their markets.* After a company has saturated its home market, growth opportunities are often better in foreign markets. Thus, such U.S. firms as Coca-Cola and McDonald's are aggressively expanding into overseas markets, and foreign firms such as Sony and Toshiba now dominate the U.S. consumer electronics market.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

2. *To seek raw materials.* Many U.S. oil companies, such as ExxonMobil, have major subsidiaries around the world to ensure access to the basic resources needed to sustain the companies' primary business lines.
3. *To seek new technology.* No single nation holds a commanding advantage in all technologies, so companies scour the globe for leading scientific and design ideas.
4. *To seek production efficiency.* Companies in high-cost countries are shifting production to low-cost regions. For example, GE has production and assembly plants in Mexico, South Korea, and Singapore; Japanese manufacturers are shifting some of their production to lower-cost countries in the Pacific Rim.
5. *To avoid political and regulatory hurdles.* For example, when Germany's BASF launched biotechnology research at home, it confronted legal and political challenges from the environmentally conscious Green movement. In response, BASF shifted its cancer and immune system research to two laboratories in the Boston suburbs. This location is attractive not only because of its large number of engineers and scientists but also because the Boston area has resolved many controversies involving safety, animal rights, and the environment.
6. *To diversify.* By establishing worldwide production facilities and markets, firms can cushion the impact of adverse economic trends in any single country. In general, geographic diversification helps because the economic ups and downs of different countries are not perfectly correlated.

WWW

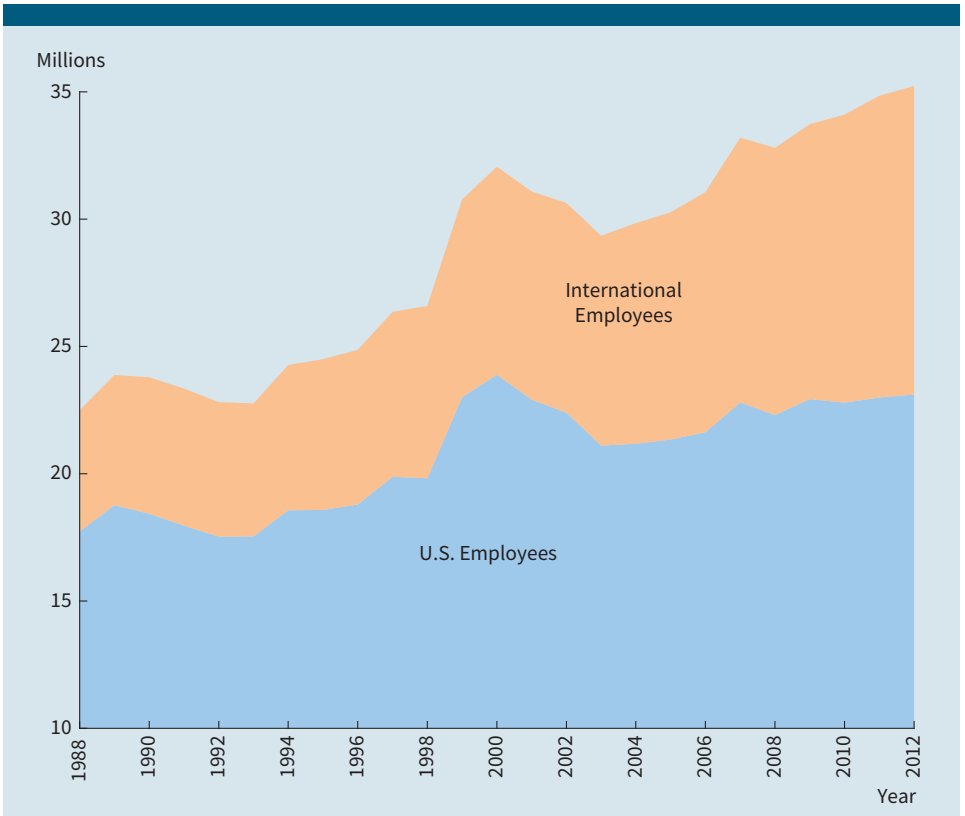
Interesting reports about the effect of trade on the U.S. economy can be found on the United States Trade Representative's home page at **www.ustr.gov.**

Figure 17-1 shows the growth in employment by U.S. multinational companies (MNCs). Notice the rapid growth between 1988 and 2000, the drop in employment during 2000 to through 2003, and the rise since then. Also notice that virtually all of the net new employees added after 2003 came from the international subsidiaries of these companies. Part of this flat employment in the United States is due to productivity gains, with the same number of employees producing more goods and services. But part is due to the growth in developing markets, which is likely to continue in the foreseeable future.

SELF-TEST

What is a multinational corporation?

Why do companies "go global"?



17-2 Multinational versus Domestic Financial Management

In theory, the concepts and procedures discussed in earlier chapters are valid for both domestic and multinational operations. However, six major factors distinguish financial management in firms operating entirely within a single country from that of firms operating globally.

1. *Different currency denominations.* Cash flows in various parts of a multinational corporate system will be denominated in different currencies. Hence, the effects of exchange rates must be addressed in all financial analyses.
2. *Economic and legal ramifications.* Each country has its own unique economic and legal system, and the differences among the systems can cause significant problems when a corporation tries to coordinate and control its worldwide operations. For example, differences in tax laws among countries can cause a given economic transaction to have strikingly different after-tax consequences, depending on where

the transaction occurs. Similarly, differences in legal systems of host nations, such as the Common Law of Great Britain versus the French Civil Law, complicate matters ranging from the simple recording of business transactions to the role played by the judiciary in resolving conflicts. Such differences can restrict multinational corporations' flexibility in deploying resources and can even make procedures that are required in one part of the company illegal in another part. These differences also make it difficult for executives trained in one country to move easily to another.

3. *Language differences*. The ability to communicate is critical in all business transactions. U.S. citizens are often at a disadvantage because they are generally fluent only in English, whereas European and Japanese businesspeople are usually fluent in several languages, including English.
4. *Cultural differences*. Even within geographic regions that are considered relatively homogeneous, different countries have unique cultural heritages that shape values and influence the conduct of business. Multinational corporations find that matters such as defining the appropriate goals of the firm, attitudes toward risk, dealings with employees, and the ability to curtail unprofitable operations vary dramatically from one country to the next.
5. *Role of governments*. In a foreign country, the terms under which companies compete, the actions that must be taken or avoided, and the terms of trade on

various transactions often are determined not in the marketplace but by direct negotiation between host governments and multinational corporations.

6. *Political risk*. A nation might place constraints on the transfer of corporate resources or even expropriate assets within its boundaries. This is political risk, and it varies from country to country. Another aspect of political risk is terrorism against U.S. firms or executives. For example, U.S. and Japanese executives are at risk of being kidnapped in Mexico and several South American countries.

These factors complicate financial management, and they increase the risks faced by multinational firms. However, the prospects for high returns and better diversification make it worthwhile for firms to accept these risks and learn how to manage them.

SELF-TEST

Identify and briefly discuss six major factors that complicate financial management in multinational firms.

17-3 Exchange Rates

WWW

The Bloomberg World Currency Values site provides up-to-the-minute foreign currency values versus the U.S. dollar. The site can be accessed at **www.bloomberg.com/markets/currencies.**

International transactions often require the purchaser to convert currency into the seller's currency. For example, a U.S. importer of wine from France might have to convert dollars into **euros**, the currency used by members of the European Monetary Union. Sometimes the reverse occurs. For example, OPEC member Saudi Arabia receives dollars for the oil it sells but must convert the dollars to riyals before spending it in Saudi Arabia. Similarly, Iran requires European and Asian countries to pay for oil in euros even though Iran's currency is the rial. Unless you regularly trade in foreign currencies, the notation can be confusing, so that is where we will begin.

17-3a Foreign Exchange Notation

An **exchange rate** specifies the number of units of a given currency that can be purchased with one unit of another currency. The exchange rate is also called the **foreign exchange rate**, the **FX rate**, and the **FOREX rate**. What does it mean if you see an exchange rate for dollars and euros posted at 1.25? Does it mean 1 dollar buys 1.25 euros or that 1 euro buys 1.25 dollars? Or if you see an exchange rate quote for dollars and the Japan yen of 80, what does that mean?

You are not the only one to ask such questions, so the International Organization for Standardization (ISO) defined specific labels for currencies. For example, the U.S. dollar is USD, the Japanese yen is JPY, and the euro is EUR. Most sources of exchange rate quotes, such as *The Wall Street Journal,* Reuters, Google Finance, and Yahoo!Finance, would report the quote as USD/JPY = 80.[1] Here is how to interpret that quote. First, it is *not* the number of dollars per yen, as you might be led to think by the slash mark between USD and JPY—in fact, it is the opposite! It is the value of a dollar when expressed in yen, or 80 yen per dollar.

Here is the logic. Suppose you are doing business in Argentina and decide at dinner to buy a nice bottle of Malbec. One of your competitors from Japan also decides to buy the same wine. You would each need to convert your currency to Argentine pesos, but a quote of USD/JPY = 80 means that your competitor would need to convert 80 yen for each

[1]Some sources report quotes slightly differently. For example, **www.bloomberg.com** would report it as USD-JPN. Some sources use currency notation, like the CFA Institute, which would report it as $:¥ = 80. But in all cases the notation shows the value of the first currency relative to the second currency.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

dollar that you convert. In other words, 1 dollar is 80 times as valuable as 1 yen. Therefore, the quote of USD/JPY shows the relative value of a dollar to a yen. If this quote were an equation, you could do some algebra and get:

$$\begin{aligned} \text{USD/JPY} &= 80 \\ \text{USD} &= 80 \text{ JPY} \\ \$1.00 &= ¥80 \end{aligned}$$

This means that 1 dollar is worth 80 yen. Just remember that the "fraction" in the notation shows the relative values of the two currencies and you will be able to keep exchange rates straight. For example, the quote of EUR/USD = 1.25 means that the euro is 25% more valuable than the dollar, so 1 euro can buy 1.25 dollars.

There are two other important concepts related to notation: home versus foreign and direct versus indirect. For example, sometimes the financial press will talk about a **foreign currency** and the **home currency** (also called the domestic currency). That is pretty straightforward—if you are in the United States and taking a U.S. perspective, then the U.S. dollar is the home currency and all other currencies are foreign currencies. Alternatively, if you are in India and taking a local perspective, the home currency is the rupee.

A **direct quote** reports the number of units of the home currency per unit of foreign currency. If we take a U.S. perspective, the quote EUR/USD = 1.25 is a direct quote because it shows the number of dollars per euro. When not shown in tables, the U.S. financial press often reports a direct quote with a dollar sign. For example, the press would report "the euro was at $1.25."

An **indirect quote** is the inverse of a direct quote and shows the number of foreign currency per unit of home currency. For example, the quote USD/JPY = 80 is an indirect quote from a U.S. perspective. When not shown in tables, the U.S. financial press often reports an indirect quote with the foreign currency symbol. For example, the press would report "the dollar was at ¥80."

For consistency throughout this chapter, we will always take the U.S. perspective. A simple mnemonic device to help you remember is that a *D*irect quote is *D*ollars per unit of foreign currency.

17-3b Converting Currencies

Table 17-1 reports recent exchange rates for several currencies. The values shown in Column 1 are direct quotes and show the number of U.S. dollars required to purchase one unit of a foreign currency. The exchange rates in Column 2 are indirect quotes.

Normal practice in currency trading centers is to use indirect quotations (Column 2) for all currencies other than British pounds and euros, for which the direct quotations are given. Thus, we speak of the pound as "selling at 1.4744 dollars, or at $1.4744," and the euro as "selling at $1.0497." For all other currencies, the normal convention is to use indirect quotations. For example, for the Japanese yen, we would quote the dollar as "being at ¥121.4200," where the "¥" stands for *yen*. This convention eliminates confusion when comparing quotations from one trading center—say, New York—with those from another—say, London or Zurich.

resource

*See **Ch17 Tool Kit.xlsx** on the textbook's Web site for all calculations.*

We can use the data in Table 17-1 to show how to work with exchange rates. Suppose a tourist flies from New York to London, then to Paris, and then on to Geneva. She then flies to Montreal, and finally back to New York. Her tour package includes lodging, food, and transportation, but she must pay for any other expenses. When she arrives at London's Heathrow Airport, she goes to the bank to check the foreign exchange listings. The rate she observes for U.S. dollars is $1.4744, which is the number of dollars

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

TABLE 17-1
Selected Exchange Rates

	Direct Quotation: U.S. Dollars Required to Buy One Unit of Foreign Currency (1)	Indirect Quotation: Number of Units of Foreign Currency per U.S. Dollar (2)
Canadian dollar	*0.7822*	1.2784
Japanese yen	*0.0082*	121.4200
Mexican peso	*0.0646*	15.4878
Swiss franc	*0.9944*	1.0056
U.K. (British) pound	1.4744	*0.6782*
Euro	1.0497	*0.9527*

Note: The financial press usually quotes British pounds and euros as direct quotations, so Column 2 equals 1.0 divided by Column 1 for these currencies. The financial press usually quotes all other currencies as indirect quotations, so Column 1 equals 1.0 divided by Column 2 for these currencies. We use italic to denote a quote that is an inverse of the actual reported quote.

Source: *The Wall Street Journal,* **http://online.wsj.com;** quotes for March 13, 2015.

per pound. Summarizing her situation, she starts with dollars, sees the exchange rate posted as dollars/pound, and wants to end with pounds. If she exchanges $3,000, how many pounds will she get?[2]

$$\frac{3{,}000 \text{ dollars}}{1.4744 \text{ dollars/pound}} = 2{,}034.73 \text{ pounds}$$

She then enjoys a short vacation in London, ending with £1,000.

After taking a train under the English Channel to France, she realizes that she needs to exchange her 1,000 remaining pounds for euros. However, what she sees on the board is the direct quotation for dollars per pound and the direct quotation for dollars per euro. The exchange rate between any two currencies other than dollars is called a **cross rate**. Cross rates are actually calculated on the basis of various currencies relative to the U.S. dollar. For example, the cross rate between British pounds and euros is computed as follows:

$$\frac{1.4744\left(\frac{\text{dollars}}{\text{pound}}\right)}{1.0497\left(\frac{\text{dollars}}{\text{euro}}\right)} = \left(\frac{1.4744}{1.0497}\right)\left(\frac{\text{dollars}}{\text{pound}}\right)\left(\frac{\text{euros}}{\text{dollar}}\right) = 1.4046 \text{ euros per pound}$$

[2]For a quick refresher in algebra, recall that:

$$\frac{aX}{b\left(\frac{X}{Y}\right)} = \left(\frac{a}{b}\right)\left(\frac{X}{\left(\frac{X}{Y}\right)}\right) = \left(\frac{a}{b}\right)\left(\frac{XY}{X}\right) = \left(\frac{a}{b}\right)Y.$$

So if a = 3,000, X = dollars, b = 1.4744, and Y = pounds, then $\frac{aX}{b\left(\frac{X}{Y}\right)} = 2{,}034.73$ pounds.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

She would receive 1.4046 euros for every British pound, so she would receive:

$$(1{,}000 \text{ pounds})\left(\frac{1.4046 \text{ euros}}{\text{pound}}\right) = 1{,}404.60 \text{ euros}$$

WWW

For a nice currency calculator to determine the exchange rate between any two currencies, see **finance.yahoo.com/currency.**

She has 800 euros remaining when she finishes touring in France and arrives in Geneva. She again needs to determine a cross rate, this time between euros and Swiss francs. The quotes she sees, as shown in Table 17-1, are a direct quote for euros (1.0497 dollars per euro) and an indirect quote for Swiss francs (1.0056 Swiss francs per dollar). To find the cross rate for Swiss francs per euro, she makes the following calculation:

$$\left(\frac{1.0556 \text{ Swiss francs}}{\text{dollar}}\right)\left(\frac{1.0497 \text{ dollars}}{\text{euro}}\right) = 1.0556 \text{ Swiss francs per euro}$$

Therefore, for every euro she would receive 1.0556 Swiss francs, so she would receive:

$$(800 \text{ euros})\left(\frac{1.0556 \text{ Swiss francs}}{\text{euro}}\right) = 844.48 \text{ Swiss francs}$$

She has 500 Swiss francs remaining when she leaves Geneva and arrives in Montreal. She again needs to determine a cross rate, this time between Swiss francs and Canadian dollars. The quotes she sees, as shown in Table 17-1, are an indirect quote for Swiss francs (1.0056 Swiss francs per dollar) and an indirect quote for Canadian dollars (1.2784 Canadian dollars per U.S. dollar). To find the cross rate for Canadian dollars per Swiss franc, she makes the following calculation:

$$\frac{1.2784\left(\frac{\text{Canadian dollars}}{\text{U.S. dollar}}\right)}{1.0056\left(\frac{\text{Swiss francs}}{\text{U.S. dollar}}\right)} = \left(\frac{1.2784}{1.0056}\right)\left(\frac{\text{Canadian dollars}}{\text{U.S. dollar}}\right)\left(\frac{\text{U.S. dollar}}{\text{Canadian dollars}}\right)$$

$$= 1.2713 \text{ Canadian dollars per Swiss franc}$$

Therefore, she would receive:

$$(500 \text{ Swiss francs})\left(\frac{1.2713 \text{ Canadian dollars}}{\text{Swiss franc}}\right) = 635.65 \text{ Canadian dollars}$$

After leaving Montreal and arriving at New York, she has 100 Canadian dollars remaining. She sees the indirect quote for Canadian dollars of 1.2784 Canadian dollars per U.S. dollar and converts the 100 Canadian dollars to U.S. dollars as follows:

$$\frac{100 \text{ Canadian dollars}}{\left(1.2784\left(\frac{\text{Canadian dollars}}{\text{U.S. dollar}}\right)\right)} = \left(\frac{100}{1.2784}\right)(\text{Canadian dollars})\left(\frac{\text{U.S. dollar}}{\text{Canadian dollars}}\right)$$

$$= 78.22 \text{ U.S. dollars}$$

In this example, we made three assumptions. First, we assumed that our traveler had to calculate the cross rates. For retail transactions, it is customary to display the cross rates directly instead of a series of dollar rates. Second, we assumed that exchange rates remain constant over time. Actually, exchange rates vary every day, often dramatically. We will have more to say about exchange rate fluctuations in the next section. Finally, we assumed that there were no transaction costs involved in exchanging currencies. In reality, small retail exchange transactions such as those in our example usually involve fixed and/or sliding-scale fees that can easily consume 5% or more of the transaction amount. However, credit card purchases minimize these fees.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Major business publications, such as *The Wall Street Journal*, and Web sites, such as **www.bloomberg.com,** regularly report cross rates among key currencies. A set of cross rates is given in Table 17-2. When examining the table, note the following points:

1. Column 1 gives indirect quotes for dollars—that is, units of a foreign currency that can be bought with one U.S. dollar. Examples: $1 will buy 0.9527 euro or 1.0056 Swiss francs. This is consistent with Table 17-1, Column 2.
2. Other columns show number of units of other currencies that can be bought with one pound, one Swiss franc, etc. For example, the euro column shows that 1 euro will buy 1.3419 Canadian dollars, 127.4546 Japanese yen, or 1.0497 U.S. dollars.
3. The rows show direct quotes—that is, the number of units of the currency of the country listed in the left column required to buy one unit of the currency listed in the top row. The bottom row is particularly important for U.S. companies, as it shows the direct quotes for the U.S. dollar. This row is consistent with Column 1 of Table 17-1.
4. Observe that the values on the bottom row of Table 17-2 are reciprocals of the corresponding values in the first column. For example, the U.K. row in the first column shows 0.6782 pound per dollar, and the pound column in the bottom row shows $1/0.6782 = 1.4744$ dollars per pound.
5. By reading down the euro column, you can see that 1 euro is worth 1.0556 Swiss francs. This is the same cross rate that we calculated for the U.S. tourist in our example.

The tie-in with the dollar ensures that all currencies are related to one another in a consistent manner—if this consistency did not exist, then currency traders could profit by buying undervalued and selling overvalued currencies. This process, known as *arbitrage*, works to bring about an equilibrium wherein the same relationship described earlier exists. Currency traders are constantly operating in the market, seeking small inconsistencies from which they can profit. The traders' existence enables the rest of us to assume that currency markets are in equilibrium and that, at any moment in time, cross rates are all internally consistent.[3]

TABLE 17-2
Key Currency Cross Rates

What is an exchange rate?

Explain the difference between direct and indirect quotations.

What is a cross rate?

Assume that the indirect quote is for 10.0 Mexican pesos per U.S. dollar. What is the direct quote for dollars per peso? **(0.10 dollars/peso)**

Assume that the indirect quote is for 115 Japanese yen per U.S. dollar and that the direct quote is for 1.25 U.S. dollars per euro. What is the yen per euro exchange rate? **(143.75 yen per euro)**

17-4 Exchange Rates and International Trade

Just as the demand for consumer goods such as Tommy Hilfiger clothing and Nike shoes changes over time, so does the demand for currency. One factor affecting currency demand is the balance of trade between two countries. For example, U.S. importers must buy yen to pay for Japanese goods, whereas Japanese importers must buy U.S. dollars to pay for U.S. goods. If U.S. imports from Japan were to exceed U.S. exports to Japan, then the United States would have a **trade balance** deficit with Japan, and there would be a greater demand for yen than for dollars. Capital movements also affect currency demand. For example, suppose interest rates in the United States were higher than those in Japan. To take advantage of high U.S. interest rates, Japanese banks, corporations, and sophisticated individuals would buy dollars with yen and then use those dollars to purchase high-yielding U.S. securities. This would create greater demand for dollars than for yen.

Without any government intervention, the relative prices of yen and dollars would fluctuate in response to changes in supply and demand in much the same way that prices of consumer goods fluctuate. For example, if U.S. consumers were to increase their demand for Japanese electronic products, then the accompanying increase in demand for the yen would cause its value to increase relative to the dollar. In this situation, the yen would be strong due to fundamental economic forces.

However, governments can and do intervene. A country's central bank can artificially prop up its currency by using its reserves of gold or foreign currencies to purchase its own currency in the open market. This creates artificial demand for its own currency, thus causing its value to be artificially high. A central bank can also keep its currency at an artificially low value by selling its own currency in the open markets. This increases the currency's supply, which reduces its price.

WWW

The International Monetary Fund reports a full listing of exchange rate arrangements. See **www.imf.org/external/data.htm.** *The IMF also publishes a more detailed listing in its* Annual Report on Exchange Arrangements and Exchange Restrictions. *For another listing of world currencies, see* **http://fx.sauder.ubc.ca/currency_table.html.**

Why might an artificially low currency be a problem? After all, a cheap currency makes it less expensive for other nations to purchase the country's goods, which creates jobs in the exporting country. However, an artificially low currency value raises the cost of imports, which increases inflation. In addition, high import prices allow competing domestic manufacturers to raise their prices as well, further boosting inflation. The government intervention that causes the artificially low value also contributes to inflation: When a government creates currency to sell in the open markets, this increases the money supply, and, all else held constant, an increasing money supply leads to still more inflation. Thus, artificially holding down the value of a currency stimulates exports but at the expense of potentially overheating and inflating the economy. Also, other countries—whose economies are being weakened because their manufacturers cannot compete against the artificially low prices—may retaliate and impose tariffs or other restrictions on the country that is holding its currency value down.

For example, China had for many years artificially held down the value of the yuan (also called the renminbi). This helped make China the world's largest exporter and

greatly stimulated its economy. However, by 2004 the Chinese economy was growing at an unsustainably high rate, and inflation was rising rapidly. The United States and other nations began urging the Chinese government to allow the yuan to rise, which would help their economies by slowing Chinese exports and stimulating their own exports to China. On July 21, 2005, the Chinese government suddenly announced that it was changing the exchange rate to allow the yuan's value to rise by 2.1%. The Chinese government has continued to allow the yuan to appreciate slowly, and it now (March 2015) stands at about 0.1614 dollars per yuan versus 0.1217 dollars per yuan in June 2005. Notice that this change has made it somewhat cheaper for Chinese to buy from America (a yuan now buys more dollars) and more expensive for Americans to buy from China.

A currency that is artificially high has the opposite effects: Inflation will be held down and citizens can purchase imported goods at low domestic prices, but exporting industries are hurt, as are domestic industries that compete with the cheap imports. Because there is relatively little external demand for the currency, the government will have to create demand by purchasing its own currency, paying with either gold or foreign currencies held by its central bank. Over time, supporting an inflated currency can deplete the gold and foreign currency reserves, making it impossible to continue propping up the currency.

The following sections describe ways that governments handle changes in currency demands.

SELF-TEST

What is the effect on a country's economy of an artificially low exchange rate? Of an artificially high exchange rate?

17-5 The International Monetary System and Exchange Rate Policies

Every nation has a monetary system and a monetary authority. In the United States, the Federal Reserve is our monetary authority, and its task is to hold down inflation while promoting economic growth and raising our national standard of living. Moreover, if countries are to trade with one another, there must be some sort of system in place to facilitate payments between nations. The international monetary system is the framework within which exchange rates are determined. As we describe in this section, there are several different policies used by various countries to determine exchange rates.[4]

17-5a A Short History Lesson: The Bretton Woods Fixed Exchange Rate System

From the end of World War II until August 1971, most of the industrialized world operated under the Bretton Woods **fixed exchange rate system** administered by the International Monetary Fund (IMF). Under this system, the U.S. dollar was linked to gold (at $35 per ounce), and other currencies were then tied to the dollar. The United States took actions to keep the price of gold at $35 per ounce, and central banks acted to

[4]For a comprehensive history of the international monetary system and details of how it has evolved, consult one of the many economics books on the subject, which include Robert Carbaugh, *International Economics,* 14th ed. (Mason, OH: South-Western Cengage Learning, 2013); Mordechai Kreinin, *International Economics: A Policy Approach,* 10th ed. (New York: Learning Solutions, 2010); Jeff Madura, *International Financial Management,* 12th ed. (Mason, OH: Cengage Learning, 2015); and Joseph P. Daniels and David D. Van Hoose, *International Monetary and Financial Economics* (Boston: Pearson, 2014).

keep exchange rates between other currencies and the dollar within narrow limits. For example, when the demand for pounds was falling, the Bank of England would step in and buy pounds to push up their price, offering gold or foreign currencies in exchange for pounds. Conversely, when the demand for pounds was too high, the Bank of England would sell pounds for dollars or gold. The Federal Reserve in the United States performed the same functions, and central banks of other countries operated similarly. These actions artificially matched supply and demand, keeping exchange rates stable, but they didn't address the underlying imbalance. For example, if the high demand for pounds occurred because British productivity was rising and British goods were improving in quality, then the underlying demand for pounds would continue in spite of central bank intervention. In such a situation, the Bank of England would find it necessary to continually sell pounds. If the central bank stopped selling pounds, then their value would rise; that is, the pound would strengthen and exceed the agreed-upon limits.

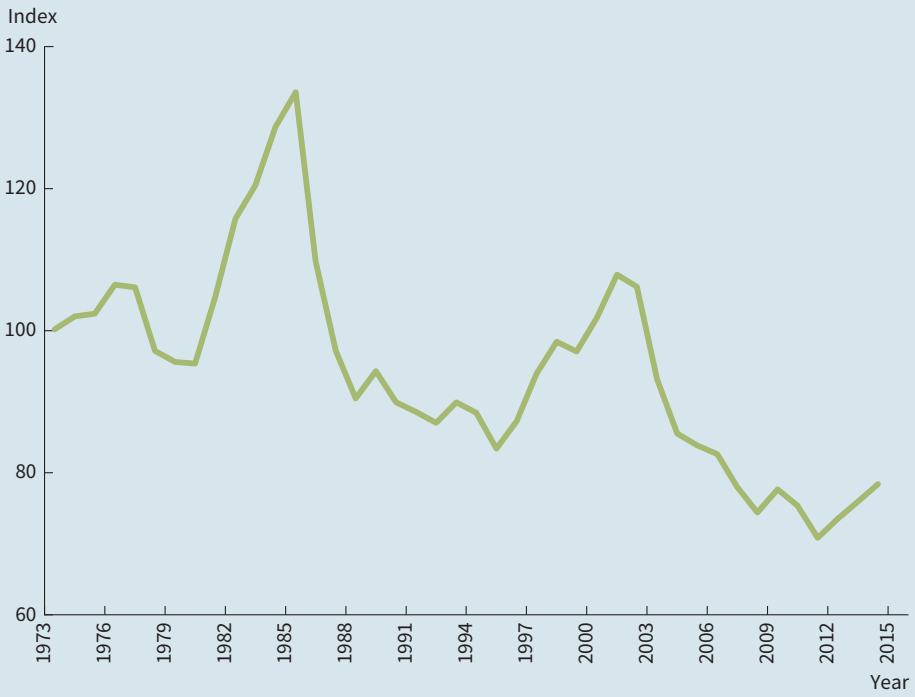
Many countries found it difficult and economically painful to maintain the fixed exchange rates required by Bretton Woods. This system began to crumble in August 1971, and it was abandoned completely by the end of 1973. The following sections describe several modern exchange rate systems.

17-5b Floating Exchange Rates

In the early 1970s, the U.S. dollar was cut loose from the gold standard and, in effect, allowed to "float" in response to supply and demand caused by international trade and international investing activities. Figure 17-2 shows the value of the U.S. dollar relative to eight major currencies since it was allowed to float. There have been some peaks when demand for the dollar was high (such as in the mid-1980s and early 2000s), but the overall trend has been down. When we wrote this in mid-2015, the dollar was near its all-time low. This bodes well for exports, but it hurts U.S. consumers.

According to the International Monetary Fund, about 65 countries operate under a system of **floating exchange rates**, in which currency prices are allowed to seek their own levels based on supply and demand. Of these, 29 have free floating exchange rates with virtually no government intervention; these currencies include the dollar, euro, pound, and yen. The other 36 float with only modest central bank intervention to smooth out extreme exchange rate fluctuations; these include Israel, India, and Peru.

CURRENCY APPRECIATION AND DEPRECIATION



Currency appreciation occurs when one currency gains value relative to another currency—in other words, the appreciating currency can buy more of the other currency than it could before appreciating. For example, suppose the current exchange rate is EUR/USD = 1.25, which means that 1 euro can buy 1.25 dollars. Suppose the euro appreciates 20% against the dollar. In this case, the euro would be able to purchase 20% more dollars, so the new exchange rate would be EUR/USD = 1.25(1 + 0.20) = 1.50, which means the euro can purchase 1.50 dollars.

It is easy to get mixed up when calculating rates of appreciation, so here are some suggestions. Notice that two currencies are involved (euros and dollar) and the euro is the one appreciating. This means we need to express the original exchange rate as the number of dollars per euro in order to find the number of dollars per euro after the appreciation.

To apply these suggestions, consider a situation in which the dollar appreciates 10% versus the euro. This means the dollar now can purchase 10% more euros, so we need to express the exchange rate as the number of euros that can be purchased by 1 dollar. We can't use the direct quote of $1.25 (which is EUR/USD = 1.25) because it is the number of dollars that can be purchased by 1 euro. Instead, we need to find the indirect quote,

FIGURE 17-2
U.S. Dollar Index versus Eight Major Currencies

Source: Data obtained from the St. Louis Federal Reserve. The Federal Reserve defines the index as "Averages of daily figures. A weighted average of the foreign exchange value of the U.S. dollar against a subset of the broad index currencies that circulate widely outside the country of issue. Major currency index includes the Euro Area, Canada, Japan, United Kingdom, Switzerland, Australia, and Sweden." See **http://research.stlouisfed.org/fred2/series/TWEXMANL?cid=105.**

which is 1/(1.25): USD/EUR = 1/1.25 = 0.80, the number of euros that 1 dollar can purchase. Now we apply the 10% appreciation rate and get the new exchange rate of USD/EUR = 0.80(1 + 0.10) = 0.88, which means that 0.88 euros can be purchased by $1.

Currency depreciation occurs when one currency loses value relative to another currency—the depreciating currency now buys less of the other currency than it could before depreciating. For example, suppose the dollar depreciates 10% with respect to the Mexican peso. We want to start with the number of pesos that 1 dollar could purchase before depreciating, so this is the indirect quote. Suppose the exchange rate is USD/MXN = 10, which is the number of pesos that can be purchased by 1 dollar. The exchange rate after the dollar depreciates is USD/MXN = 10(1 − 0.10) = 9. Therefore, the dollar is only able to purchase 10% less (9 pesos) than it could prior to depreciating.

Perhaps contrary to intuition, the percentage that one currency appreciates with respect to a second currency usually is not the same as the percentage that the second currency depreciates with respect to the first currency. To see this, consider the first example in which the euro appreciated by 20% against the dollar, with the exchange rate changing from EUR/USD = 1.25 to 1.50. Let's calculate by how much the dollar depreciated against the euro. Start by finding the indirect rates: 1/1.25 = 0.80 and 1/1.5 = 0.6667. This means that the dollar could purchase 0.80 euros before the dollar depreciated, and 0.6667 euros after it depreciated, for a change of

16.67%: $(0.80 - 0.6667)/0.80 = 0.1667 = 16.67\%$. This shows that the euro appreciated by 20% and the dollar depreciated by 16.67%. As this example shows, you need to be very careful when analyzing currency appreciation or deprecation.

EXCHANGE RATE RISK

Exchange rate fluctuations can have a profound effect on profits and trade. For example, in 2002 the euro exchange rate was about $0.87 (i.e., 0.87 dollars per euro). In 2015, the exchange rate was about $1.05. Consider the impact this has on profits and trade. For example, a hand-blown glass from the Italian island of Murano cost about €50 in 2002. Ignoring shipping costs and taxes, a consumer in the United States could have purchased this glass for €50($0.87/€) = $43.50. Assuming the price in 2015 still was €50, it would cost €50($1.05/€) = $52.50. Thus, the change in exchange rates obviously hurt Italian exports to the United States.

On the other hand, U.S. vintners were able to export wines to Italy much more profitably in 2015 than in 2002. For example, suppose a bottle of Pinot Noir cost a California vineyard $10 to produce in 2002 but could be sold for €17 in Europe. In 2002, the profit would have been €17($0.87/€) − $10 = $14.79 − $10 = $4.79. Assuming no change in production costs, the bottle's profit in 2015 is €17($1.05/€) − $10 = $17.85 − $10 = $7.85. Thus, U.S. exporters to Europe have benefited by the change in exchange rates.

The volatility of exchange rates under a floating system increases the uncertainty of the cash flows for a multinational corporation. Because its cash flows are generated in many parts of the world, they are denominated in many different currencies. When exchange rates change, the dollar-equivalent value of the company's consolidated cash flows also fluctuates. This is known as **exchange rate risk**, and it is a major factor differentiating a global company from a purely domestic one.

17-5c Pegged Exchange Rates

In a **pegged exchange rate** system, a country locks, or "pegs," its currency's exchange rate to another currency or basket of currencies. It is common for a country with a pegged exchange rate to allow its currency to vary within specified limits or bands (often set at ±1% of the target rate) before the country intervenes to force the currency back within the limits.

The IMF estimates that 83 countries use this type of approach. Examples in which a currency is pegged to another country's currency include Bhutan's ngultrum, which is pegged to the Indian rupee; the Falkland Islands' pound, which is pegged to the British pound; and Barbados' dollar, which is pegged to the U.S. dollar. An example of a currency being pegged to a basket is China, where the yuan is no longer just pegged to the U.S. dollar but rather to a basket of currencies. The Chinese government will not reveal exactly which currencies make up the basket, but the U.S. dollar, the euro, the yen, and the South Korean won are certainly components.

CURRENCY DEVALUATION AND REVALUATION

As indicated previously, countries with pegged exchange rates establish a fixed exchange rate with some other major currency or basket of currencies. When a government reduces its target fixed exchange rate, the result is currency **devaluation**; increasing the rate results in currency **revaluation**. For example, from 1991 through early 2002, Argentina had a fixed exchange rate of 1 peso per U.S. dollar. Imports were high, exports were low, and the Argentinean government had to purchase huge amounts of pesos to maintain that artificially high exchange rate. The government borrowed heavily to finance these purchases, and eventually it was unable to continue supporting the peso. (Indeed, the

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. government defaulted on some of its obligations.) As a result, the government had to devalue the peso to 1.4 pesos per dollar in early 2002. Notice that this made the peso weaker: Before the devaluation, 1 peso would buy 1 dollar, but afterward 1 peso would buy only 71 cents (1.4 pesos per dollar $= 1/1.4 = 0.71$ dollar per peso). The devaluation lowered the prices of Argentine goods on the world market, which helped its exporters, but prices rose for imported goods, including oil. The initial shock to the Argentine economy was severe, as employment fell in those industries that were not exporters. The problem was exacerbated because many Argentine companies and individuals had incurred debt that was denominated in dollars, which instantly cost much more to service. However, the economy gradually improved, aided by increased exports, tourism, and employment rates. Still, the initial pain caused by devaluation helps explain why many countries with fixed exchange rates tend to postpone needed measures until economic pressures build to explosive levels.

Given the expense of maintaining an artificially high exchange rate and the pain of large devaluations, many countries that once had pegged exchange rates now allow their currencies to float. For example, Mexico had a pegged exchange rate prior to 1994, but it depleted its foreign reserves trying to support the peso and was forced to devalue it. Mexico's currency now floats, as does that of Argentina.

CONVERTIBLE VERSUS NONCONVERTIBLE SECURITIES

A pegged exchange rate isn't necessarily a deterrent to direct investment in the country by foreign corporations—as long as the local government's central bank supports the currency and devaluations are unlikely. This was generally the case in the Bretton Woods era, so those currencies were considered to be **convertible currencies** because the nation that issued them allowed them to be traded in the currency markets and was willing to redeem them at market rates. This is true today for all floating-rate currencies, which are also called **hard currencies** because of their convertibility. Some pegged currencies are also at least partially convertible, because their central banks will redeem them at market rates under specified conditions.

However, some countries set the exchange rate but do not allow their currencies to be traded freely on world markets. For example, the Chinese yuan is allowed to float in a very narrow band against a basket of securities. However, the yuan can be legally used and exchanged only within China. Furthermore, the Chinese government imposes restrictions on both residents and nonresidents from freely converting their holdings of yuans into another currency. Thus, the yuan is a **nonconvertible currency**, also called a **soft currency**.

Most countries with nonconvertible currencies allow foreign companies to convert foreign currency into the local nonconvertible currency. For example, a U.S. parent company might establish a foreign subsidiary, convert dollars into the nonconvertible currency, and open a business in the country with the "nonconvertible" currency. The problem occurs when the subsidiary generates cash flow denominated in the local currency. The parent would like the subsidiary to convert the cash flow into dollars and transfer it back to the parent, a process called **repatriation**. However, the country with nonconvertible currency might place severe restrictions on repatriation or not allow it all. If repatriation is allowed, the official exchange rate might be so low that the converted dollars will not have much purchasing power back in the United States.

In addition to impeding business, a nonconvertible currency also harms the country's citizens who might wish to travel abroad, study abroad, or make purchases denominated in dollars or another convertible currency. Citizens can purchase foreign currency at the official exchange rate, which might not provide much purchasing power, or they can turn to black markets. Neither alternative is attractive.

17-5d Managed Floating Rates

In a **managed floating rate** system, there is significant government intervention to manage the exchange rate by manipulating the currency's supply and demand. The government rarely reveals its target exchange rate levels if it uses a managed float regime because this would make it too easy for currency speculators to profit. According to the IMF, about 48 countries have a managed floating rate system, including Costa Rica, Malaysia, and Russia.

17-5e No Local Currency

A few countries don't have their own separate legal tender but instead use the currency of another nation. For example, Ecuador has used the U.S. dollar since September 2000.

Other countries belong to a monetary union, such as the 19 European Monetary Union nations in 2015 whose currency is the euro, which is allowed to float. In contrast, member nations of the Eastern Caribbean Currency Union, the West African Economic and Monetary Union (WAEMU), and the Central African Economic and Monetary Community (CAEMC) use their respective unions' currencies, which are themselves pegged to some other currency. For example, the Eastern Caribbean dollar is pegged to the U.S. dollar, and the CFA franc (used by both the WAEMU and CAEMC) is pegged to the euro.[5]

SELF-TEST

What is the difference between a fixed exchange rate system and a floating rate system?

What are pegged exchange rates?

What does it mean to say that the dollar is depreciating with respect to the euro?

What is a convertible currency?

17-6 Trading in Foreign Exchange

Importers, exporters, tourists, and governments buy and sell currencies in the foreign exchange market. For example, when a U.S. trader imports automobiles from Japan, payment will probably be made in Japanese yen. The importer buys yen (through its bank) in the foreign exchange market, which consists of a network of brokers and banks based in New York, London, Tokyo, and other financial centers. Almost all transactions are conducted by computer and telephone.

WWW

Currency futures prices are available from the Chicago Mercantile Exchange (CME) on its Web site at **www.cme.com.** *Currency spot and forward rates are available from FXStreet at* **www.fxstreet.com/rates-charts/forward-rates.**

17-6a Spot Rates and Forward Rates

The exchange rates shown in Tables 17-1 and 17-2 are known as **spot rates**, which mean the rate paid for delivery of the currency "on the spot" or, in reality, no more than 2 days after the day of the trade. For most of the world's major currencies, it is also possible to buy (or sell) currencies for delivery at some agreed-upon future date, usually 30, 90, or 180 days from the day the transaction is negotiated. This rate is known as the **forward exchange rate**.

[5]A few countries, such as Bosnia and Herzegovina, have currency board arrangements. Under this system, a country technically has its own currency but commits to exchange it for a specified foreign money unit at a fixed exchange rate. This requires it to impose domestic currency restrictions unless it has the foreign currency reserves to cover requested exchanges.

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

For example, suppose that a U.S. firm must pay 500 million yen to a Japanese firm in 30 days and that the current spot rate is 121.4200 yen per dollar. If spot rates remain constant, then the U.S. firm will pay the Japanese firm the equivalent of $4.118 million (500 million yen divided by 121.4200 yen per dollar) in 30 days. But if the spot rate falls to, say, 110 yen per dollar, then the U.S. firm will have to pay the equivalent of 4.545 million: $4.545 = (500 yen)(110 ¥/$). If the spot rate increases to 134, the firm will pay only $3.731 million: $3.731 = (500 yen)(134 ¥/$).

The treasurer of the U.S. firm can avoid exposure to this variability by entering into a 30-day forward exchange contract. Suppose this contract promises delivery of yen to the U.S. firm in 30 days at a guaranteed price of 120.8700 yen per dollar. No cash changes hands at the time the treasurer signs the forward contract, although the U.S. firm might have to put some collateral down as a guarantee against default. Yet because the firm can use an interest-bearing instrument for the collateral, this requirement is not costly. The counterparty to the forward contract must deliver the yen to the U.S. firm in 30 days, and the U.S. firm is obligated to purchase the 500 million yen at the previously agreed-upon rate of 120.8700 yen per dollar. Therefore, the treasurer of the U.S. firm is able to lock in a payment equivalent to $4.137 million = (500 million yen)(120.8700 ¥/$), no matter what happens to spot rates. This technique is called *hedging*.

Forward rates for 30-, 90-, and 180-day delivery, along with the current spot rates for some commonly traded currencies, are given in Table 17-3. If you can obtain *more* of the foreign currency for a dollar in the forward than in the spot market, then the forward foreign currency is less valuable than the spot foreign currency and the forward currency is said to be selling at a **discount**. In other words, if the foreign currency is expected to depreciate (based on the forward rates) with respect to the home currency, then the forward currency is at a discount. Conversely, because a dollar would buy *fewer* yen and francs in the forward than in the spot market, the forward yen and francs are selling at a **premium**.

TABLE 17-3
Selected Spot and Forward Exchange Rates, Indirect Quotation: Number of Units of Foreign Currency per U.S. Dollar

		Forward Rates[a]			
	Spot Rate	30 Days	90 Days	180 Days	Forward Rate at a Premium or Discount[b]
Canada (Dollar)	1.2784	1.2790	1.2801	1.2812	Discount
Japan (Yen)	121.42	120.87	119.96	118.04	Premium
Switzerland (Franc)	1.0056	1.0044	1.0021	0.9979	Premium

Notes:

[a] Traders quote forward rates in pips (Percentage in Points). A pip is the smallest digit in which a currency is quoted. For example, the Swiss franc is quoted out to 4 decimal places, so 1 pip is equal to 0.0001, which is 1/10,000. The pip divisor is 10,000 for the Swiss franc. For the yen, the pip divisor is 100 (i.e., 1 pip is equal to 0.01) because the yen is quoted only to two decimal places. The quote is the number of pips represented by the forward rate minus the spot. For example, the quote for the 30-day forward rate for the Swiss franc was −12.2 pips. This means the forward rate calculation is equal to the spot rate plus pips/divisor: 1.0056 + (−12.2/10,000) = 1.00438, rounded to 1.0044. For the yen, the quote was −55.5 pips. The forward rate calculation is: 121.42 + (−55.5/100) = 120.865 rounded to 120.87.

[b] When it takes more units of a foreign currency to buy a dollar in the future, then the value of the foreign currency is less in the forward market than in the spot market; hence, the forward rate is at a *discount* to the spot rate. When it takes fewer units of a foreign currency to buy a dollar in the future, the forward rate is at a *premium*. If using indirect quotes, a higher forward rate is at a discount and a lower forward rate is at a premium.

Source: Spot rates are from *The Wall Street Journal* for March 13, 2015, as reported in Table 17-1. Forward rates are determined from quotes from FXStreet on March 13, 2015, at **www.fxstreet.com.**

SELF-TEST

Differentiate between spot and forward exchange rates.

Explain what it means for a forward currency to sell at a discount and at a premium.

17-7 Interest Rate Parity

Market forces determine whether a currency sells at a forward premium or a discount, and the general relationship between spot and forward exchange rates is specified by a concept called "interest rate parity."

Interest rate parity means that investors should expect to earn the same return on security investments in all countries after adjusting for risk. It recognizes that when you invest in a country other than your home country, you are affected by two factors—returns on the investment itself and changes in the exchange rate. It follows that your overall return will be higher than the investment's stated return if the currency in which your investment is denominated appreciates relative to your home currency. Likewise, your overall return will be lower if the foreign currency that you receive declines in value.

To illustrate interest rate parity, consider the case of a U.S. investor who can buy default-free 180-day Swiss bonds that promise a 4% nominal annual return. The 180-day foreign (Swiss) interest rate, r_f, is $4\% \div 2 = 2\%$ because 180 days is one-half of a 360-day year. Assume also that the indirect quotation for the spot exchange rate is 1.0056 Swiss francs per dollar, as shown in Table 17-3. Finally, assume that the 180-day forward exchange rate is 0.9979 Swiss francs per dollar, which means that in 180 days the investor can exchange 1 dollar for 0.9979 Swiss francs.

The U.S. investor could receive a 4% annualized return denominated in Swiss francs, but if he ultimately wants to consume goods in the United States, then those Swiss francs must be converted to dollars. The dollar return on the investment depends, therefore, on what happens to exchange rates over the next 6 months. However, the investor can lock in the dollar return by selling the foreign currency in the forward market. For example, the investor could simultaneously do the following:

1. Convert \$1,000 to 1005.60 Swiss francs in the spot market: \$1,000 (1.0056 Swiss francs per dollar) = 1005.60 Swiss francs.
2. Invest the Swiss francs in a 180-day Swiss bond that has a 4% annual return, or a 2% semiannual return. This investment will pay $1005.60(1.02) = 1025.71$ Swiss francs in 180 days.
3. Agree today to exchange the Swiss francs in 180 days at the forward rate of 0.9979 Swiss francs per dollar, for a total of (1025.71 Swiss francs) ÷ (0.9979 Swiss francs per dollar) = \$1,027.869.

Hence, this investment has an expected 180-day return in dollars of $\$27.87/\$1{,}000 = 2.787\%$, which translates into a nominal annual return of $2(2.787\%) = 5.574\%$. In this case, the expected 5.574% return consists of 4% from the Swiss bond itself plus 1.574% because the market believes that the Swiss franc will strengthen relative to the dollar. Observe that, by locking in the forward rate today, the investor has eliminated all exchange rate risk. And because the Swiss bond is assumed to be default-free, the investor is certain to earn a 5.574% annual dollar return.

Interest rate parity implies that an investment in the United States with the same risk as the Swiss bond should also have a return of 5.574%. When we express interest rates as periodic rates, we can express interest rate parity by the following equation (later in the chapter we will use a slightly different version of interest rate parity when we consider multi-year cash flows):

$$\frac{\text{Forward exchange rate}}{\text{Spot exchange rate}} = \frac{1 + r_h}{1 + r_f} \quad \textbf{(17-1)}$$

Here, r_h is the periodic interest rate in the home country, r_f is the periodic interest rate in the foreign country, and the forward and spot exchange rates are expressed as direct quotations (that is, units of home currency per unit of foreign currency).

Using Table 17-3, the direct spot quotation is 0.99443 dollars per Swiss franc =(1/1.0056 Swiss francs per dollar), and the direct 180-day forward quotation is $1.00210 = (1/0.9979)$. Using Equation 17-1, we can solve for the equivalent home rate, r_h:

$$\frac{\text{Forward exchange rate}}{\text{Spot exchange rate}} = \frac{1 + r_h}{1 + r_f} = \frac{1 + r_h}{1 + 0.02} = \frac{1.100210}{0.99443} \quad \textbf{(17-1a)}$$

$$1 + r_h = \left(\frac{1.00210}{0.99443}\right)(1 + 0.02) = 1.027867$$

The periodic home interest rate is 2.78678%, and the annualized home interest rate is $(2.7867\%)(2) = 5.573\%$, the same value we found before except for a slight difference due to rounding.

After accounting for exchange rates, interest rate parity states that bonds in the home country and the foreign country must have the same actual rate of return in the investor's currency. In this example, the U.S. bond must yield 5.573% to provide the same return as the 4% Swiss bond. If one bond provides a higher return, then investors will sell their low-return bond and flock to the high-return bond. This activity will cause the price of the low-return bond to fall (which pushes up its yield) and the price of the high-return bond to increase (driving down its yield). These effects will continue until the two bonds again have the same returns after accounting for exchange rates.

In other words, interest rate parity implies that an investment in the United States with the same risk as a Swiss bond should have a dollar value return of 5.573%. Solving for r_h in Equation 17-1, we indeed find that the predicted interest rate in the United States is 5.573%, the same return except for the slight rounding difference.

Interest rate parity shows why a particular currency might be at a forward premium or discount. Note that a currency is at a forward premium whenever domestic interest rates are higher than foreign interest rates. Discounts prevail if domestic interest rates are lower than foreign interest rates. If these conditions do not hold, then arbitrage will soon force interest rates and exchange rates back to parity.

SELF-TEST

What is interest rate parity?

Assume that interest rate parity holds. When a currency trades at a forward premium, what does that imply about domestic rates relative to foreign interest rates? What does it imply when a currency trades at a forward discount?

Assume that 90-day U.S. securities have a 4.5% annualized interest rate whereas 90-day Swiss securities have a 5% annualized interest rate. In the spot market, 1 U.S. dollar can be exchanged for 1.2 Swiss francs. If interest rate parity holds, what is the 90-day forward rate exchange between U.S. and Swiss francs? **(0.8323 $/SFr or 1.2015 SFr/$)**

On the basis of your answer to the previous question, is the Swiss franc selling at a premium or discount on the forward rate? **(Discount)**

17-8 Purchasing Power Parity

We have discussed exchange rates in some detail, and we have considered the relationship between spot and forward exchange rates. However, we have not yet addressed the fundamental question: What determines the spot level of exchange rates in each country? Although exchange rates are influenced by a multitude of factors that are difficult to predict, particularly on a day-to-day basis, market forces over the long run work to ensure that similar goods sell for similar prices in different countries after taking exchange rates into account. This relationship is known as "purchasing power parity."

Purchasing power parity (PPP), sometimes referred to as the *law of one price,* implies that the levels of exchange rates and prices adjust so as to cause identical goods to cost the same amount in different countries. For instance, if a pair of tennis shoes costs $150 in the United States and 100 pounds in Britain, then PPP implies that the exchange rate must be $1.50 per pound. Consumers could purchase the shoes in Britain for 100 pounds, or they could exchange their 100 pounds for $150 and then purchase the same shoes in the United States at the same effective cost (assuming no transaction or transportation costs). Here is the equation for purchasing power parity:

$$P_h = (P_f)(\text{Spot rate}) \quad (17\text{-}2)$$

or

$$\text{Spot rate} = \frac{P_h}{P_f} \quad (17\text{-}3)$$

Here

P_h = The price of the good in the home country ($150 in our example, assuming the United States is the home country).

P_f = The price of the good in the foreign country (100 pounds).

Note that the spot market exchange rate is expressed as the number of units of home currency that can be exchanged for one unit of foreign currency ($1.50 per pound).

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Purchasing power parity assumes that market forces will eliminate situations in which the same product sells at a different price overseas. For example, if the shoes cost $140 in the United States, then importers/exporters could purchase them in the United States for $140, sell them for 100 pounds in Britain, exchange the 100 pounds for $150 in the foreign exchange market, and earn a profit of $10 on every pair of shoes. Ultimately, this trading activity would increase the demand for shoes in the United States and thus raise P_h, increase the supply of shoes in Britain and thus reduce P_f, and increase the demand for dollars in the foreign exchange market and thus reduce the spot rate. Each of these actions works to restore PPP.

Note that PPP assumes that there are no transportation or transaction costs and no import restrictions, all of which limit the ability to ship goods between countries. In many cases, these assumptions are incorrect, which explains why PPP is often violated. An additional problem for empirical tests of the PPP theorem is that products in different countries are rarely identical. There are frequently real or perceived differences in quality that can lead to price differences in different countries.

Still, the concepts of interest rate parity and purchasing power parity are vitally important to those engaged in international activities. Companies and investors must anticipate changes in interest rates, inflation, and exchange rates, and they often try to hedge the risks of adverse movements in these factors. The parity relationships are extremely useful when anticipating future conditions.

SELF-TEST

What is meant by purchasing power parity?

A computer sells for $1,500 U.S. dollars. In the spot market, $1 = 115 Japanese yen. If purchasing power parity holds, what should be the price (in yen) of the same computer in Japan? **(¥172,500)**

Hungry for a Big Mac? Go to Ukraine!

Purchasing power parity (PPP) implies that the same product will sell for the same price in every country after adjusting for current exchange rates. One problem when testing to see if PPP holds is that it assumes that goods consumed in different countries are of the same quality. For example, if you find that a product is more expensive in Switzerland than it is in Canada, one explanation is that PPP fails to hold, but another explanation is that the product sold in Switzerland is of a higher quality and therefore deserves a higher price.

One way to test for PPP is to find goods that have the same quality worldwide. With this in mind, *The Economist* magazine occasionally compares the prices of a well-known good whose quality is the same in nearly 120 different countries: the McDonald's Big Mac hamburger.

In early 2015, a Big Mac cost about $4.79 in the United States but could be purchased for about $1.20 in Ukraine after converting dollars to the Ukrainian hryvnia. *The Economist* "backed out" the exchange rate implied by the purchasing power parity relationship and calculated that the hryvnia was undervalued by about 71.5%. In other words, the hryvnia would have to appreciate against the dollar by about 75% for the PPP relationship to hold. At the other extreme, a Big Mac sold for the equivalent of $7.54 in Switzerland. If the PPP relationship holds, then the Swiss franc is overvalued relative to the dollar by about 57%.

If the PPP relationship holds, then the Big Mac test suggests that there is an opportunity for investors to profit by shorting the Swiss franc and going long in the hryvnia. We don't suggest that you do this, but we do recommend that you avoid Big Macs if you travel in Switzerland.

17-9 Inflation, Interest Rates, and Exchange Rates

WWW

For current international interest rates, go to **www.bloomberg.com** *and select Market Data. Then select Rates and Bonds.*

Relative inflation rates, or the rates of inflation in foreign countries compared with that in the home country, have many implications for multinational financial decisions. Obviously, relative inflation rates will greatly influence future production costs at home and abroad. Equally important, inflation has a dominant influence on relative interest rates and exchange rates. Both of these factors influence decisions by multinational corporations for financing their foreign investments, and both have an important effect on the profitability of foreign investments.

The currencies of countries with higher inflation rates than that of the United States will by definition *depreciate* over time against the dollar. Countries where this has occurred include Mexico and all the South American nations. On the other hand, the currencies of Switzerland and Japan, which have had less inflation than the United States, have generally *appreciated* against the dollar. In fact, *a foreign currency will, on average, depreciate or appreciate against the U.S. dollar at a percentage rate approximately equal to the amount by which its inflation rate exceeds or is less than the U.S. rate*.

Relative inflation rates also affect interest rates. The interest rate in any country is largely determined by its inflation rate. Therefore, countries currently experiencing higher rates of inflation than the United States also tend to have higher interest rates. The reverse is true for countries with lower inflation rates.

It is tempting for a multinational corporation to borrow in countries with the lowest interest rates. However, this is not always a good strategy. Suppose, for example, that interest rates in Switzerland are lower than those in the United States because of Switzerland's lower inflation rate. A U.S. multinational firm could therefore save interest by borrowing in Switzerland. However, because of relative inflation rates, the Swiss franc will probably appreciate in the future, causing the dollar cost of annual interest and principal payments on Swiss debt to rise over time. Thus, *the lower interest rate could be more than offset by losses from currency appreciation*. Similarly, multinational corporations should not necessarily avoid borrowing in a country such as Brazil, where interest rates have been very high, because future depreciation of the Brazilian real could make such borrowing end up being relatively inexpensive.

SELF-TEST

What effects do relative inflation rates have on relative interest rates?

What happens over time to the currencies of countries with higher inflation rates than that of the United States? To those with lower inflation rates?

Why might a multinational corporation decide to borrow in a country such as Brazil, where interest rates are high, rather than in a country like Switzerland, where interest rates are low?

17-10 International Money and Capital Markets

From World War II through the 1960s, the U.S. capital markets dominated world markets. Today, however, the value of U.S. securities represents less than one-fourth the value of all securities. Many corporations are finding that international markets often offer better opportunities for raising or investing capital than are available domestically. The growth of the international markets has also opened up opportunities for investors. One way for U.S. citizens to invest in world markets is to buy the stocks of U.S. multinational corporations that invest directly in foreign countries. Another way is to purchase foreign securities—stocks, bonds, or money market instruments issued by foreign companies. Security investments are known as *portfolio investments,* and they are distinguished from *direct investments* in physical assets by U.S. corporations.

Greasing the Wheels of International Business

What do bribery and tax shelters have in common? Both are targets of international regulation.

Thirty-seven countries have now signed the Organization for Economic Cooperation and Development's Anti-Bribery Convention. This requires each country to pass legislation making it a crime for companies to bribe public officials. The United States, which signed the convention, has been the most aggressive in prosecuting violators. It is interesting that this prosecution has not been limited to U.S. companies but also has extended to foreign companies whose stocks are listed in the United States. For example, Statoil, a Norwegian firm, was fined $10.5 million in 2006 for bribing Iranian officials. Subsidiaries of Vetco International, headquartered in the United Kingdom, were fined $26 million in 2007 for bribing Nigerian officials. Siemens, a German company, holds the record for the largest fine paid to date (2012), with over *$1.6 billion* paid to regulatory agencies in the United States and Germany.

Among the international organizations striving to reform global taxation and eliminate tax-shelter abuse are the Joint International Tax Shelter Information Centre, the Seven Country Working Group, and the Leeds Castle Group. Their goals include improving transparency, eliminating double taxation, and abolishing tax havens.

What does the reformation of tax havens have in common with the elimination of bribery? First, both of these problems distract companies from focusing on their core business issues, and both create uneven playing fields where providing the best product at the best price isn't as important as who you know (and bribe!) or how clever your lawyers are. Second, these problems reduce transparency in capital markets, making it harder for investors to identify the best firms. When investors are uncertain about a company, the cost of capital goes up. Thus, there is a direct link between transparency and a company's ability to raise capital at a fair price.

17-10a Eurodollar Market

A **Eurodollar** is a U.S. dollar deposited in a bank outside the United States. (Although they are called Eurodollars because they originated in Europe, Eurodollars are actually any dollars deposited in any part of the world other than the United States.) The bank in which the deposit is made may be a non-U.S. bank, such as Barclays Bank in London; the foreign branch of a U.S. bank, such as Citibank's Paris branch; or even a foreign branch of a third-country bank, such as Barclays' Munich branch. Most Eurodollar deposits are for $500,000 or more, and they have maturities ranging from overnight to about 1 year.

The major difference between Eurodollar deposits and regular U.S. time deposits is their geographic locations. The two types of deposits do not involve different currencies—in both cases, dollars are on deposit. However, Eurodollars are outside the direct control of the U.S. monetary authorities, so U.S. banking regulations, including reserve requirements and FDIC insurance premiums, do not apply. The absence of these costs means that the interest rate paid on Eurodollar deposits can be higher than domestic U.S. rates on equivalent instruments.

The dollar is the leading international currency. However, British pounds, euros, Swiss francs, Japanese yen, and other currencies are also deposited outside their home countries; these *Eurocurrencies* are handled in exactly the same way as Eurodollars.

Eurodollars are borrowed by U.S. and foreign corporations for various purposes but especially to pay for goods imported from the United States and to invest in U.S. security markets. Also, U.S. dollars are used as an international currency or medium of exchange, and many Eurodollars are also used for this purpose. It is interesting to note that Eurodollars were actually "invented" by the Soviets in 1946. International merchants did not trust the Soviets or their rubles, so the Soviets bought some dollars (for gold),

deposited them in a Paris bank, and then used these dollars to buy goods in the world markets. Others found it convenient to use dollars this same way, and soon the Eurodollar market was in full swing.

Eurodollars are usually held in interest-bearing accounts. The interest rate paid on these deposits depends: (1) on the bank's lending rate, because the interest a bank earns on loans determines its willingness and ability to pay interest on deposits, and (2) on rates of return available on U.S. money market instruments. If money market rates in the United States were above Eurodollar deposit rates, then these dollars would be sent back and invested in the United States; if U.S. rates were lower than Eurodollar deposit, which is more often the case, then more dollars would be sent out of the United States to become Eurodollars. Given the existence of the Eurodollar market and the electronic flow of dollars to and from the United States, it is easy to see why interest rates in the United States cannot be insulated from those in other parts of the world.

Interest rates on Eurodollar deposits (and loans) are tied to a standard rate known by the acronym **LIBOR**, which stands for **London Interbank Offered Rate**. LIBOR is the rate of interest offered by the largest and strongest London banks on dollar deposits of significant size. On April 3, 2015, LIBOR rates were well above domestic U.S. bank rates on time deposits of the same maturity—0.12% for 3-month CDs versus 0.27% for LIBOR CDs. The Eurodollar market is essentially a short-term market; most loans and deposits are for less than 1 year.

17-10b International Bond Markets

Any bond sold outside the country of the borrower is called an **international bond**. The Bank for International Settlements reports that over $21 trillion international bonds are outstanding, with 40% denominated in dollars and 41% in Euros; British pounds, Japanese yen, Swiss francs, and Australian dollars account for most of the rest. There are two important types of international bonds: foreign bonds and Eurobonds.

Foreign bonds are bonds sold by a foreign borrower but denominated in the currency of the country in which the issue is sold. For instance, Nortel Networks (a Canadian company) may need U.S. dollars to finance the operations of its subsidiaries in the United States. If it decides to raise the needed capital in the United States, then the bond would be underwritten by a syndicate of U.S. investment bankers, denominated in U.S. dollars, and sold to U.S. investors in accordance with SEC and applicable state regulations. Except for the foreign origin of the borrower, this bond would be indistinguishable from those issued by equivalent U.S. corporations. However, because Nortel is a foreign corporation, the bond would be a foreign bond. Furthermore, because it is denominated in dollars and sold in the United States under SEC regulations, it is also called a **Yankee bond**. In contrast, if Nortel issued bonds in Mexico that were denominated in pesos, then they would be foreign bonds, not Yankee bonds.

The term **Eurobond** is used to designate any bond issued in one country but denominated in the currency of some other country. Examples include a Ford Motor Company issue denominated in dollars and sold in Germany and a British firm's sale of euro-denominated bonds in Switzerland. Issuers include multinational firms, international financial institutions, national governments, and even some purely domestic U.S. firms, which often find they can lower their debt costs by borrowing overseas.

The institutional arrangements for issuing Eurobonds are different from those of purely domestic bond issues, with the most important distinction being a far lower level of required disclosure, especially when compared with bonds issued in the United States. Governments tend to be less strict when regulating securities denominated in foreign currencies, because the bonds' purchasers are generally more "sophisticated." The lower disclosure requirements result in lower total transaction costs to issue Eurobonds.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Although centered in Europe, global syndicates of investment banks underwrite and sell Eurobonds to investors from all parts of the world, not just Europe. Eurobonds appeal to investors for several reasons. Generally, they are issued in bearer form rather than as registered bonds, so the names and nationalities of investors are not recorded. Individuals who desire anonymity, whether for privacy reasons or for tax avoidance, like Eurobonds. Similarly, most governments do not withhold taxes on interest payments associated with Eurobonds. If the investor requires an effective yield of 10%, then a Eurobond that is exempt from tax withholding would simply need a coupon rate of 10%. Another type of bond—for instance, a domestic issue subject to a 30% withholding tax on interest paid to foreigners—would need a coupon rate of 14.3% to yield an after-withholding rate of 10%. Investors who desire secrecy would not want to file for a refund of the tax, so they would prefer to hold the Eurobond.

17-10c International Stock Markets

New issues of stock are sold in international markets for a variety of reasons. For example, a non-U.S. firm might sell an equity issue in the United States because it can tap a much larger source of capital than in its home country. Also, a U.S. firm might tap a foreign market because it wants to create an equity market presence to accompany its operations in that country. Large multinational companies also occasionally issue new stock simultaneously in multiple countries. For example, Alcan Aluminum, a Canadian company, issued new stock in Canada, Europe, and the United States simultaneously, using different underwriting syndicates in each market.

Stock trading is truly global, with shares of large multinational U.S. companies traded worldwide on multiple international exchanges. U.S. investors can also invest in foreign companies through American Depository Receipts (ADRs), which are certificates representing ownership of foreign stock held in trust. Many ADRs trade on U.S. stock exchanges, including Toyota (Japan), Alibaba (China), and Anheuser-Busch InBev (Belgium).[6]

17-10d Sovereign Debt

Sovereign debt is the total amount that a government owes. Economics courses on public finance cover government debt in detail, but government debt also has an enormous impact on the topics we address in this book, including interest rates, risk, credit availability to nonfinancial corporations, and corporate valuation. Following is a brief overview of sovereign debt along with some key insights that managers should keep in mind.

Countries with well-developed economies usually issue debt denominated in their own currencies, but lesser developed countries often issue debt denominated in a foreign currency. Some government debt offerings are governed only by the issuing country's judicial system, which often does not provide much protection for lenders. However, most government debt is issued under the auspices of international law (or the laws of the borrowing country) and we focus only on this type of sovereign debt.

Most government debt is held by financial institutions, pension funds, mutual funds, hedge funds, and individual investors. However, a few governments, such as China, actually own significant amounts of other governments' debt. Let's take a look at some facts, and then draw some implications for managers and investors.

[6]For an interesting discussion of ADRs and the costs faced by listing companies when the ADR is underwritten by investment banks, see Hsuen-Chi Chen, Larry Fauver, and Pei-Ching Yang, "What Do Investment Banks Charge to Underwrite American Depository Receipts?" *Journal of Banking and Finance*, April 2009, pp. 609–618.

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

First, how much sovereign debt are we talking about? The Organisation for Economic Co-operation and Development (OECD) reported about $49 trillion in total government debt for 31 developed countries for 2013.[7] The United States owes about 36% of this total, and Japan owes about 21% of the total, followed by Germany and Italy, and then France, the United Kingdom, Germany, and Spain (each of which owes between 3% and 7% of the total).

In terms of the United States, the total federal debt as of early 2015 is about $18.2 trillion, with about $13.1 trillion called public debt because it is owed to investors; the rest is owed to other U.S. government entities, such as the Social Security Trust fund.[8] Foreign investors own about $6.2 trillion in U.S. Treasury securities. Of this, China alone owns over $1.2 trillion, or about 10% of the U.S. public debt.

Government debt can be used to invest in infrastructure, such as the highways, which are expected to "pay off" in the future with higher productivity, higher gross domestic product (GDP), and higher tax collections. However, governments can also use debt to finance deficit spending on items that aren't really investments. Such stimulus spending can help an economy avoid a recession, but it dampens economic growth in the long run.

How much debt is too much? To put it another way, how much debt is likely to lead to missed payments to lenders, default, or restructuring? One indicator is the ratio of a country's debt to its GDP. Table 17-4 reports estimated ratios for the end of 2013 for the 48 highest of the 160 countries reported by the *CIA World Factbook*. The median ratio of all reported countries is 45.6%. While no particular level of debt/GDP guarantees a problem, it is no coincidence that several of the Eurozone countries facing problems (Greece, Italy, Ireland, and Portugal) have high ratios.

TABLE 17-4
Government Debt: Public Debt as a Percentage of Gross Domestic Product

Country	Public Debt/ GDP (%)	Country	Public Debt/ GDP (%)	Country	Public Debt/ GDP (%)
Japan	226	Puerto Rico	97	Malta	75
Zimbabwe	202	Spain	94	Belize	75
Greece	175	France	93	Netherlands	73
Italy	133	Egypt	92	United States	72
Iceland	131	United Kingdom	91	Slovenia	72

Even more telling is the change in the ratio over time. Greece went from a ratio of around 110% in 2004 to 165% by 2012. With a ratio that high, it should be no surprise that in late 2009 Greece began facing the possibility of defaulting on its debt. Because the debt is denominated in euros, Greece's problem was also the European Monetary Union's (EMU) problem. In addition to bailout loans from the EMU far exceeding €100 billion, Greek bond investors agreed in 2012 to restructure the debt, which essentially reduced the value of the debt by a little over 50% of its original face value.

The Eurozone crisis was not over when we wrote this in mid-2015. Greek citizens, angry over austerity measures imposed as conditions of the bailouts, had elected a new government. At this point in time, it is not even sure that Greece will continue to use the euro, which would have enormous consequences for the rest of the EMU and the world.

Interconnected global economies and financial markets mean that one country's problems often affect the rest of the world. For example, the flat economic outlook in the Eurozone is a drag on growth in China and other exporters to Europe, including the United States.

Stock Market Indices around the World

In the United States, the Dow Jones Industrial Average (^DJI) is the most well-known stock market index. Similar indices also exist for each major world financial center. As shown in the accompanying table, India's market has had the strongest performance during the past 10 years while Japan's has had the weakest.

Hong Kong (^HSI)

In Hong Kong, the primary stock index is the Hang Seng. Created by HSI Services Limited, the Hang Seng index is composed of 33 large stocks.

Great Britain (^FTSE)

The FT-SE 100 Index (pronounced "footsie") is the most widely followed indicator of equity investments in Great Britain. It is a value-weighted index composed of the 100 largest companies on the London Stock Exchange.

Japan (^N225)

In Japan, the principal barometer of stock performance is the Nikkei 225 Index. The index consists of highly liquid equity issues thought to be representative of the Japanese economy.

Germany (^GDAXI)

The Deutscher Aktienindex, commonly called the DAX, is an index composed of the 30 largest companies trading on the Frankfurt Stock Exchange.

India (^BSESN)

Of the 22 stock exchanges in India, the Bombay Stock Exchange (BSE) is the largest, with more than 6,000 listed stocks and approximately two-thirds of the country's total trading volume. Established in 1875, the exchange is also the oldest in Asia. Its yardstick is the BSE Sensex, an index of 30 publicly traded Indian stocks that account for one-fifth of the BSE's market capitalization.

Notes: For easy access to world indices, see **http://finance.yahoo.com/m2** and use the ticker symbols shown above in parentheses.

Relative 10-Year Performance (Starting Values = 100)

	United States	Germany	Great Britain	Hong Kong	India	Japan
April 2005	100	100	100	100	100	100
April 2015	175	275	139	187	425	166

17-11 Multinational Capital Budgeting

Until now we've discussed the general environment in which multinational firms operate. In the remainder of the chapter, we see how international factors affect key corporate decisions, beginning with capital budgeting. Although the same basic principles apply to capital budgeting for both foreign and domestic operations, there are some key differences. These include the types of risks faced by the firm, cash flow estimation, and project analysis.[9]

17-11a Risk Exposure

Foreign projects may be more or less risky than equivalent domestic projects, and that can lead to differences in the cost of capital. Higher risk for foreign projects tends to result from two primary sources: (1) exchange rate risk and (2) political risk. However, international diversification might result in a lower risk.

Exchange rate risk concerns the value of the basic cash flows in the parent company's home currency. Foreign currency cash flows turned over to the parent must be converted into U.S. dollars, so projected cash flows must be translated to dollars at the expected future exchange rates. An analysis should be conducted to ascertain the effects of exchange rate variations on dollar cash flows; then, on the basis of this analysis, an exchange rate risk premium should be added to the domestic cost of capital. It is sometimes possible to hedge against exchange rate risk, but it may not be possible to hedge completely, especially on long-term projects. If hedging is used, then the costs of doing so must be subtracted from the project's operating cash flows.

Political risk refers to potential actions by a host government that would reduce the value of a company's investment. It includes at one extreme expropriation of the subsidiary's assets without compensation, but it also includes less drastic actions that reduce the value of the parent firm's investment in the foreign subsidiary.[10] These actions include higher taxes, tighter repatriation or currency controls, and restrictions on prices charged. The risk of expropriation is small in traditionally friendly and stable countries such as Great Britain or Switzerland. However, in Latin America, Africa, the Far East, and Eastern Europe, the risk may be substantial. Past expropriations include those of ITT and

[9]Many domestic companies form joint ventures with foreign companies; see Insup Lee and Steve B. Wyatt, "The Effects of International Joint Ventures on Shareholder Wealth," *Financial Review*, November 1990, pp. 641–649. For a discussion of the Japanese cost of capital, see Jeffrey A. Frankel, "The Japanese Cost of Finance," *Financial Management*, Spring 1991, pp. 95–127. For a discussion of financial practices in the Pacific basin, see George W. Kester, Rosita P. Chang, and Kai-Chong Tsui, "Corporate Financial Policy in the Pacific Basin: Hong Kong and Singapore," *Financial Practice and Education*, Spring/Summer 1994, pp. 117–127.

Consumer Finance in China

The financial frontier for consumer finance is in China, where applicants must often wait more than a month to get a credit card and even longer for car loans or home mortgages. But that is changing quickly, as GE Money (formerly known as GE Capital) is among a host of financial players looking to partner with or become part owners of Chinese banks. Other foreign investors include financial institutions from all over the world, such as Citigroup (United States), Voya Financial (Netherlands), Hang Seng Bank (Hong Kong), and the Royal Bank of Scotland. Even investment banks (Goldman Sachs) and private equity firms (Newbridge Capital) are in the hunt.

What makes Chinese banks attractive? First, China is now allowing foreign-owned banks to make direct loans to Chinese customers. Second, China has a huge consumer base with a growing middle class that is purchasing homes, cars, and other consumer goods. Third, many Chinese banks might be considered "fixer-uppers" because they hold too many uncollectible loans (up to 9.2% of their loan portfolios), have weak information technology systems, and provide poor customer service. GE Money, which brings considerable business expertise (in addition to cash) to the partnership, views these problems as opportunities. For example, GE Money helped Shenzhen Development Bank (SDB) introduce a Walmart credit card, an Auchen credit card (Auchen is a large French retailer), and various mortgage services. All the results aren't yet in, but GE has helped SDB reduce the time to get a credit card from over a month to just 5 days.

Investing in China isn't without risks, with an estimated 60% of partnerships not providing the return that was anticipated at the deal's inception. Problems include insufficient pre-deal planning, a lack of focus and traction in the immediate post-deal period, a failure to integrate cultures, and a lack of flexibility in adapting to local conditions. Still, the potential rewards are enormous, so you should expect to see more foreign investment in China.

Source: Don Durfee, "Give Them Credit," *CFO*, July 2007, pp. 50–57.

Anaconda Copper in Chile; Gulf Oil in Bolivia; Occidental Petroleum in Libya; Enron Corporation in Peru; BP, ConocoPhillips, ExxonMobil, and Chevron in Venezuela; and the assets of many companies in Iraq, Iran, and Cuba.

Note that companies can take steps to reduce the potential loss from expropriation, including one or more of the following:

1. Finance the subsidiary with local capital.
2. Structure operations so that the subsidiary has value only as a part of the integrated corporate system.
3. Obtain insurance against economic losses from expropriation from a source such as the Overseas Private Investment Corporation (OPIC).

If OPIC insurance is purchased, then the premiums paid must be added to the project's cost.

Several organizations rate countries according to different aspects of risk. For example, Transparency International (TI) ranks countries based on perceived corruption, which is an important part of political risk. Table 17-5 shows selected countries. Denmark is rated by TI as the most honest country, while Somalia is the most dishonest. The United States is ranked seventeenth.

17-11b Cash Flow Estimation

Cash flow estimation is more complex for foreign than domestic investments. Most multinational firms set up separate subsidiaries in each foreign country in which they operate, and the relevant cash flows for the parent company are the dividends and royalties paid by the subsidiaries to the parent, translated into dollars. Dividends and royalties are normally taxed by both foreign and home country governments, although the

home country may allow credits for some or all of the foreign taxes paid. Furthermore, a foreign government may restrict the amount of the cash that may be repatriated to the parent company. For example, some governments place a ceiling, stated as a percentage of the company's net worth, on the amount of cash dividends that a subsidiary can pay to its parent. Such restrictions normally are intended to force multinational firms to reinvest earnings in the foreign country, although restrictions are sometimes imposed to prevent large currency outflows, which might disrupt the exchange rate.

Whatever the host country's motivation for blocking repatriation of profits, the result is that the parent corporation cannot use cash flows blocked in the foreign country to pay dividends to its shareholders or to invest elsewhere in the business. Hence, from the perspective of the parent organization, the cash flows relevant for foreign investment analysis are the cash flows that the subsidiary is actually expected to send back to the parent. Note, though, that if returns on investments in the foreign country are attractive and if blockages are expected to be lifted in the future, then current blockages may not be bad; however, dealing with this situation does complicate the process of cash flow estimation.

Some companies attempt to circumvent repatriation restrictions (and to lower their taxes) through transfer pricing. For example, a foreign subsidiary might obtain raw materials or other input components from the parent. The price the subsidiary pays the parent is called a **transfer price**. If the transfer price is high then the foreign subsidiary's costs will be high, leaving little or no profit to repatriate. However, the parent's profit will be higher because it sold to the subsidiary at an inflated transfer price. The net result is that the parent receives cash flows from the subsidiary via transfer pricing rather than as repatriated dividends. Transfer pricing also can be used to shift profits from high-tax to low-tax jurisdictions. Of course, governments are well aware of these possibilities, so governmental auditors are on guard to prevent abusive transfer pricing.

Double Irish with a Dutch Twist

Untapped consumer markets, access to natural resources, and low production costs in foreign countries aren't the only reasons U.S. corporations open foreign subsidiaries. Consider the case of Google Inc., the search engine and online advertising company. In 2010, Google reported $29.3 billion in sales on its consolidated income statement. Out of this total, about $12.5 billion were from Google's wholly owned international subsidiaries. Had these sales been realized by Google's domestic operations, they would have been subject to U.S. taxes at rates up to 35%. However, through the use of a complicated tax haven known as the "Double Irish" and the "Dutch Sandwich," Google managed to pay only 2.7%. Here's how it works.

First, Google establishes an Irish subsidiary that operates in the Bahamas (we'll call this the Irish/Bahamas subsidiary). The Bahamas have no corporate income taxes, and Ireland has special tax laws that make tax havens possible. Google transfers the licensing rights to use its search engine technology to this subsidiary, and this is where all the profits from international sales will end up. Next, the Bahamas subsidiary establishes a subsidiary that operates in the Netherlands. The Netherlands is special because even though it requires corporate taxes to be paid, it allows easy transfers to the Bahamas. The Netherlands subsidiary then establishes an Irish subsidiary that operates in Ireland and is assigned all the revenues from advertising sales. The Bahamas and Netherlands subsidiaries may even have zero employees while the Irish subsidiary has some employees, but not very many, because virtually all of the services are provided by U.S. employees.

Complicated? You bet! Google owns the Irish/Bahamas subsidiary, which owns the Netherlands subsidiary, which owns the Irish subsidiary. When advertising revenue from sales made in, say, Britain comes in, the Irish subsidiary receives these. However, it makes very little profit and therefore pays very little tax to Ireland because it pays a huge licensing fee to its parent, the Netherlands subsidiary, which, in turn makes little profit because it pays a huge licensing fee to its parent, the Irish/Bahamas subsidiary. And because the Bahamas has no corporate income tax, no tax is due on these profits.

So how might Google's shareholders ultimately benefit if profits remain in the Bahamas? The Bahamas subsidiary might someday pay a dividend to Google, at which point the profits would be taxed at Google's U.S. corporate tax rate. At that point, Google might pay a dividend to stockholders. In the interim, though, Google uses these profits, which have been taxed at almost a zero tax rate, to invest in international operations. And if, at some future point in time, Congress passes a law like it did in 2004 allowing corporations a one-time opportunity to repatriate earnings at a reduced tax rate, then that money will end up back in U.S. Google's hands.

Google's tax deferral strategy is legal, and many companies use it, including Oracle Corp., Facebook, Eli Lilly, and Pfizer. Whether it is good public policy for Congress to allow these shelters to exist is another matter entirely. Even though the Bahamas subsidiary earns higher profits because its net tax rate is almost zero, these profits don't help U.S. employment or other U.S. businesses because they aren't used for investment in the United States. It is estimated that these shelters reduce U.S. tax revenues by roughly $60 billion per year, an amount that would make a significant dent in the government deficit. The U.S. Treasury and Congress considered restricting them in 2009, but heavy lobbying from such companies as GE, Hewlett-Packard, and Starbucks convinced Congress not to make the changes.

17-11c Project Analysis

Consider a domestic project that requires foreign raw materials, or one where the finished product will be sold in a foreign market. Because the operation is based in the United States, any projected nondollar cash flows—costs of raw materials and revenues of the finished product—should be converted into dollars. This conversion does not present much of a problem for cash flows to be paid or received in the short run, but there is a significant problem in estimating exchange rates for converting long-term foreign cash

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. flows into dollars because forward exchange rates are usually not available for more than 180 days into the future. However, long-term expected forward exchange rates can be estimated using the idea behind the interest rate parity relationship. For example, if a foreign cash flow is expected to occur in 1 year, then the 1-year forward exchange rate can be estimated using domestic and foreign government bonds maturing in 1 year. Similarly, the 2-year exchange rate can be estimated using 2-year bonds. Thus, foreign cash flows can be converted into dollars and added to the project's other projected cash flows, and then the project's NPV can be calculated based on its cost of capital.

Now consider a project to be based overseas, so that most expected future cash flows will be denominated in a foreign currency. Two approaches can be used to estimate such a project's NPV. Both begin by forecasting the future cash flows denominated in the foreign currency and then determining the annual repatriations to the United States, denominated in the foreign currency. Under the first approach, we convert the expected future repatriations to dollars (as described earlier) and then find the NPV using the project's cost of capital. Under the second approach, we take the projected repatriations (denominated in the foreign currency) and then discount them at the foreign cost of capital, which reflects foreign interest rates and relevant risk premiums. This produces an NPV denominated in the foreign currency, which can be converted into a dollar denominated NPV using the spot exchange rate.

The following example illustrates the first approach. A U.S. company has the opportunity to lease a manufacturing facility in Great Britain for 3 years. The company must spend £20 million initially to refurbish the plant. The expected net cash flows from the plant for the next 3 years, in millions, are $CF_1 = £7$, $CF_2 = £9$, and $CF_3 = £11$. A similar project in the United States would have a risk-adjusted cost of capital of 10%. The first step is to estimate the expected exchange rates at the end of 1, 2, and 3 years using the multi-year interest rate parity equation:

$$\text{Expected t-year forward exchange rate} = (\text{Spot exchange rate})\left(\frac{1 + r_h}{1 + r_f}\right)^t \quad \textbf{(17-4)}$$

where the exchange rates are expressed in direct quotations and the interest rates are expressed as annual rates, not periodic rates. (Recall that the direct quote is for units of home currency per unit of foreign currency.) We are using the interest rate parity equation to estimate expected forward rates because market-based forward rates for maturities longer than a year are generally not available.

Suppose the spot exchange rate is 1.8000 dollars per pound. Interest rates on U.S. and U.K. government bonds are shown below, along with the expected forward rate implied by the multi-year interest rate parity relationship in Equation 17-4:

	Maturity (Years)		
	1	**2**	**3**
r_h (annualized)	2.0%	2.8%	3.5%
r_f (annualized)	4.6%	5.0%	5.2%
Spot rate ($/£)	1.8000	1.8000	1.8000
Expected forward rate based on Equation 17-4 ($/£)	1.7553	1.7254	1.7141

The current dollar cost of the project is £20(1.8000 $/£) = $36 million. The Year-1 cash flow in dollars is £7(1.7553 $/£) = $12.29 million. Table 17-6 shows the complete time line and the net present value of $2.18 million.

TABLE 17-6
Net Present Value of International Investment (Cash Flows in Millions)

	Year			
	0	1	2	3
Cash flows in pounds	−£20	£7	£9	£11
Expected exchange rates (dollars/pound)	1.8000	1.7553	1.7254	1.7141
Cash flows in dollars	−$36.00	$12.29	$15.53	$18.86
Project cost of capital	10%			
NPV	$2.18			

SELF-TEST

List some key differences in capital budgeting as applied to foreign versus domestic operations.

What are the relevant cash flows for an international investment: the cash flow produced by the subsidiary in the country where it operates, or the cash flows in dollars that it sends to its parent company?

Why might the cost of capital for a foreign project differ from that of an equivalent domestic project? Could it be lower?

What adjustments might be made due to exchange rate risk and political risk to the domestic cost of capital for a foreign investment?

The current exchange rate is 1.1 dollars per euro. A 5-year U.S. government bond has a 3% yield and a 5-year French government bond has a yield of 4%. What is the expected 5-year forward rate? **(1.0481 dollars per euro)**

The current exchange rate is 0.8000 Swiss francs per dollar. A 5-year U.S. government bond has a 3% yield and a 5-year Swiss government bond has a yield of 2%. What is the expected 5-year forward rate? **(0.7619 Swiss francs per dollar)** Hint: *Remember that the interest rate parity equation is for direct quotes.*

17-12 International Capital Structures

Companies' capital structures vary among countries. For example, the Organisation for Economic Co-operation and Development (OECD) reported that, on average, Japanese firms use 85% debt to total assets (in book value terms), German firms use 64%, and U.S. firms use 55%. One problem when interpreting these numbers is that different countries often use different accounting conventions with regard to: (1) reporting assets on the basis of historical versus replacement cost, (2) the treatment of leased assets, (3) pension plan funding, and (4) capitalizing versus expensing R&D costs. These differences make it difficult to compare capital structures.

A study by Raghuram Rajan and Luigi Zingales of the University of Chicago attempted to account for differences in accounting practices.[11] In their study, Rajan and Zingales used a database that covered fewer firms than the OECD but that provided a more complete breakdown of balance sheet data. They concluded that differences in accounting practices can explain much of the cross-country variation in capital structures.

For example, when Rajan and Zingales measure capital structure as interest-bearing debt to total assets, German firms use less leverage than U.S. firms, a different result

[11]See Raghuram Rajan and Luigi Zingales, "What Do We Know about Capital Structure? Some Evidence from International Data," *Journal of Finance*, Vol. 50, No. 5, December 1995, pp. 1421–1460.

compared to the OECD report. What explains these conflicting results? Rajan and Zingales argue that much of the difference is explained by the way German firms account for pension liabilities. German firms generally include all pension liabilities (and their offsetting assets) on the balance sheet, whereas firms in other countries (including the United States) generally "net out" pension assets and liabilities on their balance sheets. To see the importance of this difference, consider a firm with $10 million in liabilities (not including pension liabilities) and $20 million in assets (not including pension assets). Assume that the firm has $10 million in pension liabilities that are fully funded by $10 million in pension assets. Therefore, net pension liabilities are zero. If this firm were in the United States, it would report a ratio of total liabilities to total assets equal to 50% ($10 million/$20 million). By contrast, if this firm operated in Germany, both its pension assets and liabilities would be reported on the balance sheet. The firm would have $20 million in liabilities and $30 million in assets—or a 67% ($20 million/$30 million) ratio of total liabilities to total assets. Total debt is the sum of short-term debt and long-term debt and *excludes* other liabilities, including pension liabilities. Therefore, the measure of total debt to total assets provides a more comparable measure of leverage across different countries.

Rajan and Zingales also make a variety of adjustments that attempt to control for other differences in accounting practices. The effects of these adjustments suggest that companies in Germany and the United Kingdom tend to have less leverage, and that firms in Canada appear to have more leverage, than firms in the United States, France, Italy, and Japan. This conclusion is supported by the average times-interest-earned ratio for firms in a number of different countries. Recall from Chapter 3 that the times-interest-earned ratio is the ratio of operating income (EBIT) to interest expense. This measure indicates how much cash the firm has available to service its interest expense. In general, firms with more leverage have a lower times-interest-earned ratio. The data indicate that this ratio is highest in the United Kingdom and Germany and lowest in Canada.

SELF-TEST

Are there international differences in firms' financial leverage? Explain.

17-13 Multinational Working Capital Management

Working capital management in a multinational setting involves more complexity than purely domestic working capital management. We discuss some of these differences in this section.

17-13a Cash Management

The goals of cash management in a multinational corporation are similar to those in a purely domestic corporation: (1) to speed up collections, slow down disbursements, and thus maximize net float; (2) to shift cash as rapidly as possible from those parts of the business where it is not needed to those parts where it is needed; and (3) to maximize the risk-adjusted, after-tax rate of return on temporary cash balances. Multinational companies use the same general procedures for achieving these goals as domestic firms, but the longer distances and more serious mail delays make such devices as lockbox systems and electronic funds transfers especially important.

Although multinational and domestic corporations have the same objectives and use similar procedures, multinational corporations face a far more complex task. As noted earlier in our discussion of political risk, foreign governments often place restrictions on transfers of funds out of the country. So even though IBM can transfer money from its Salt Lake City office to its New York concentration bank just by pressing a few buttons,

a similar transfer from its Buenos Aires office is far more complex. Buenos Aires funds must be converted to dollars before the transfer. If there is a shortage of dollars in Argentina or if the Argentinean government wants to conserve dollars so they will be available for the purchase of strategic materials, then conversion, and hence the transfer, may be blocked. Even if no dollar shortage exists in Argentina, the government may still restrict funds outflows if those funds represent profits or depreciation rather than payments for purchased materials or equipment, because many countries—especially those that are less developed—want profits reinvested in the country in order to stimulate economic growth.

Once it has been determined what funds can be transferred, the next task is to get those funds to locations where they will earn the highest returns. Whereas domestic corporations tend to think in terms of domestic securities, multinationals are more likely to be aware of investment opportunities around the world. Most multinational corporations use one or more global concentration banks, located in money centers such as London, New York, Tokyo, Zurich, or Singapore, and their staffs in those cities, working with international bankers, are able to take advantage of the best rates available anywhere in the world.

17-13b Credit Management

Consider the international cash conversion cycle for a foreign company importing from the United States: The order is placed, the goods are shipped, an account payable is created for the importer and an account receivable is created for the exporter, the goods arrive in the foreign country, the importer sells them, and the importer collects on the sales. At some point in this process, the importer pays off the account payable, which is usually before the importer collects on its own sales. Notice that the importer must finance the transaction from the time it pays the account payable until it collects on its sales. In many poorer, less-developed nations, the capital markets are not adequate to enable the importer to finance the cash conversion cycle. Even when foreign capital markets are available, the additional shipping time might lengthen the cash conversion cycle to such an extent that the importer can't afford the financing costs. Thus, there is enormous pressure on the exporter to grant credit, often with very long payment periods.

But now consider the situation from the exporter's point of view. First, it is much more difficult for the exporter to perform a credit analysis on a foreign customer. Second, the exporter also must worry about exchange rate fluctuations between the time of the sale and the time the receivable is collected. For example, if IBM sold a computer to a Japanese customer for 90 million yen when the exchange rate was 90 yen to the dollar, IBM would obtain 90,000,000/90 = $1,000,000 for the computer. However, if it sold the computer on terms of net/6 months and if the yen then fell against the dollar, so that 1 dollar would now buy 112.5 yen, IBM would end up realizing only 90,000,000/112.5 = $800,000 when it collected the receivable. Hedging with forward contracts can reduce this exchange rate risk, but what about the credit risk?

One possibility is for the importer to obtain a letter of credit from its bank whereby the bank certifies that the importer will meet the terms of the account payable or else the bank will pay. However, the importer often must pay the bank a relatively large fee for the letter of credit, and letters of credit might not be available to companies in developing countries.

A second option is for the importer essentially to write a check to the exporter at the time of the purchase, but to postdate the check so that it cannot be cashed until the account payable's due date. If the importer's bank promises that it will "accept" the check even if there are insufficient funds in the importer's account, then the check becomes a financial instrument called a **banker's acceptance**. If the bank is strong, then this

virtually eliminates the credit risk. In addition, the exporter can then sell this banker's acceptance in the secondary market if it needs funds immediately. Of course, it must sell the banker's acceptance at a discount to reflect the time value of money, because the banker's acceptance is essentially a short-term financial security that pays no interest, similar to a T-bill. Financing an international transaction via a banker's acceptance has many benefits for the exporter, but the importer often must pay the bank a relatively large fee, and this service might not be available to companies in developing countries.

A third alternative is for the exporter to purchase export credit insurance, in which an insurer makes a commitment to pay the exporter even if the importer defaults. Sometimes the "insurer" is a government agency, such as the Japanese Ministry of International Trade and Industry (MITI) or the United States Export-Import Bank. Other times, the insurer is a private insurance company. These large insurance companies have developed expertise in international credit analysis, and they can spread the risk over a large number of customers. These advantages allow them to offer credit insurance at rates that often make it less costly than either letters of credit or bankers' acceptances. In fact, export credit insurance has been so successful that it has virtually killed the market for bankers' acceptances and has become the primary way in which companies manage the credit risk of international sales.

17-13c Inventory Management

As with most other aspects of finance, inventory management for a firm in a multinational setting is similar to but more complex than for a purely domestic firm. First, there is the matter of the physical location of inventories. For example, where should ExxonMobil keep its stockpiles of crude oil and refined products? It has refineries and marketing centers located worldwide, and one alternative is to keep items concentrated in a few strategic spots from which they can then be shipped as needs arise. Such a strategy might minimize the total amount of inventories needed and thus might minimize the investment in inventories. Note, though, that consideration will have to be given to potential delays in getting goods from central storage locations to user locations all around the world. Both working stocks and safety stocks would have to be maintained at each user location as well as at the strategic storage centers. Problems like the Iraqi occupation of Kuwait in 1990 and the subsequent trade embargo, which brought with it the potential for a shutdown of production of about 25% of the world's oil supply, complicate matters further.

Exchange rates also influence inventory policy. If a local currency—say, the Danish krone—were expected to rise in value against the dollar, then a U.S. company operating in Denmark would want to increase stocks of local products before the rise in the krone, and vice versa if the krone were expected to fall.

Another factor that must be considered is the possibility of import or export quotas or tariffs. For example, Apple was buying certain memory chips from Japanese suppliers at a bargain price. Then U.S. chipmakers accused the Japanese of dumping chips in the U.S. market at prices below cost, and they sought to force the Japanese to raise their prices.[12]

[12]The term "dumping" warrants explanation, because the practice can be so important in international markets. Suppose Japanese chipmakers have excess capacity. A particular chip has a variable cost of $25, and its "fully allocated cost," which is the $25 plus total fixed cost per unit of output, is $40. Now suppose the Japanese firm can sell chips in the United States at $35 per unit, but if it charges $40, then it won't make any sales because U.S. chipmakers sell for $35.50. If the Japanese firm sells at $35, it will cover variable costs plus make a contribution to fixed overhead, so selling at $35 makes sense. Continuing, if the Japanese firm can sell in Japan at $40 but U.S. firms are excluded from Japanese markets by import duties or other barriers, then the Japanese will have a huge advantage over U.S. manufacturers. This practice of selling goods at lower prices in foreign markets than at home is called "dumping." U.S. firms are required by antitrust laws to offer the same price to all customers and, therefore, cannot engage in dumping.

This led Apple to increase its chip inventory. Then computer sales slacked off, and Apple ended up with an oversupply of obsolete computer chips. As a result, Apple's profits were hurt and its stock price fell, demonstrating once more the importance of careful inventory management.

As mentioned earlier, another danger in certain countries is the threat of expropriation. If that threat is large, then inventory holdings will be minimized and goods will be brought in only as needed. Similarly, if the operation involves extraction of raw materials such as oil or bauxite, processing plants may be moved offshore rather than located close to the production site.

Taxes have two effects on multinational inventory management. First, countries often impose property taxes on assets, including inventories; when this is done, the tax is based on holdings as of a specific date, such as January 1 or March 1. Such rules make it advantageous for a multinational firm: (1) to schedule production so that inventories are low on the assessment date, and (2) if assessment dates vary among countries in a region, to hold safety stocks in different countries at different times during the year.

Finally, multinational firms may consider the possibility of at-sea storage. Oil, chemical, grain, and other companies that deal in a bulk commodity that must be stored in some type of tank can often buy tankers at a cost not much greater—or perhaps even less, considering land cost—than land-based facilities. Loaded tankers can then be kept at sea or at anchor in some strategic location. This eliminates the danger of expropriation, minimizes the property tax problem, and maximizes flexibility with regard to shipping to areas where needs are greatest or prices highest.

This discussion has only scratched the surface of inventory management in the multinational corporation—the task is much more complex than for a purely domestic firm. However, the greater the degree of complexity, the greater the rewards from superior performance, so if you are willing to take challenges along with potentially high rewards, then look to the international arena.

SELF-TEST

What are some factors that make cash management more complicated in a multinational corporation than in a purely domestic corporation?

Why is granting credit riskier in an international context?

Why is inventory management especially important for a multinational firm?

SUMMARY

Multinational companies have more opportunities, but they also face more risks than do companies that operate only in their home market. This chapter discussed many of the key trends affecting the global markets today, and it described the most important differences between multinational and domestic financial management. The key concepts are listed here.

- A multinational, transnational, or **global corporation** is a firm that operates in an integrated fashion in a number of countries.
- Companies "go global" for these reasons: (1) to expand their markets, (2) to obtain raw materials, (3) to seek new technology, (4) to lower production costs, (5) to avoid trade barriers, and (6) to diversify.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- Several major factors distinguish financial management as practiced by domestic firms from that practiced by multinational corporations: (1) different currency denominations, (2) different economic and legal structures, (3) languages, (4) cultural differences, (5) role of governments, and (6) political risk.
- When discussing **exchange rates**, the number of U.S. dollars required to purchase one unit of a foreign currency is called a **direct quotation**, while the number of units of foreign currency that can be purchased for one U.S. dollar is an **indirect quotation**.
- Prior to August 1971, the world was on a **fixed exchange rate system** whereby the U.S. dollar was linked to gold and other currencies were then tied to the dollar. After August 1971, the world monetary system changed to a **floating system** under which major world currency rates float with market forces, largely unrestricted by governmental intervention. The central bank of each country does operate in the foreign exchange market, buying and selling currencies to smooth out exchange rate fluctuations, but only to a limited extent.
- **Pegged exchange rates** occur when a country establishes a fixed exchange rate with a major currency. Consequently, the values of pegged currencies move together over time.
- A **convertible currency** is one that may be readily exchanged for other currencies at market prices.
- **Spot rates** are the rates paid for delivery of currency "on the spot," whereas the **forward exchange rate** is the rate paid for delivery at some agreed-upon future date—usually 30, 90, or 180 days from the day the transaction is negotiated. The forward rate can be at either a **premium** or a **discount** to the spot rate.
- **Interest rate parity** holds that investors should expect to earn the same risk-free return in all countries after adjusting for exchange rates.
- **Purchasing power parity**, sometimes referred to as the *law of one price,* implies that the level of exchange rates adjusts so that identical goods cost the same in different countries.
- Granting credit to a supplier is more risky in an international context because, in addition to the normal risks of default, the multinational firm must worry about exchange rates changing between the time a sale is made and the time a receivable is collected.
- Credit policy is important for a multinational firm for two reasons: (1) Much trade is with less-developed nations, and in such situations granting credit is a necessary condition for doing business. (2) The governments of nations such as Japan, whose economic health depends on exports, often help their firms compete by granting credit to foreign customers.
- Foreign investments are similar to domestic investments, but political risk and exchange rate risk must be considered. **Political risk** is the risk that the foreign government will take some action that will decrease the value of the investment; **exchange rate risk** is the risk that a transaction in a foreign currency will be more costly than anticipated due to possible future fluctuations in exchange rates.
- The relevant cash flows in international capital budgeting are the dollars that can be **repatriated** to the parent company.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- **Eurodollars** are U.S. dollars deposited in banks outside the United States. Interest rates on Eurodollars are tied to **LIBOR**, the **London Interbank Offered Rate**.
- U.S. firms often find that they can raise long-term capital at a lower cost outside the United States by selling bonds in the international capital markets. International bonds may be either (1) **foreign bonds**, which are exactly like regular domestic bonds except that the issuer is a foreign company; or (2) **Eurobonds**, which are bonds sold in a foreign country but denominated in the currency of the issuing company's home country.

QUESTIONS

(17-1) Define each of the following terms:

a. Multinational corporation
b. Exchange rate; fixed exchange rate system; floating exchange rate
c. Trade deficit; devaluation; revaluation
d. Exchange rate risk; convertible currency; pegged exchange rate
e. Interest rate parity; purchasing power parity
f. Spot rate; forward exchange rate; discount on forward rate; premium on forward rate
g. Repatriation of earnings; political risk
h. Eurodollar; Eurobond; international bond; foreign bond
i. The euro

(17-2) Under the fixed exchange rate system, what was the currency against which all other currency values were defined? Why?

(17-3) Exchange rates fluctuate under both the fixed exchange rate and floating exchange rate systems. What, then, is the difference between the two systems?

(17-4) If the Swiss franc depreciates against the U.S. dollar, can a dollar buy more or fewer Swiss francs as a result?

(17-5) If the United States imports more goods from abroad than it exports, then foreigners will tend to have a surplus of U.S. dollars. What will this do to the value of the dollar with respect to foreign currencies? What is the corresponding effect on foreign investments in the United States?

(17-6) Why do U.S. corporations build manufacturing plants abroad when they could build them at home?

(17-7) Should firms require higher rates of return on foreign projects than on identical projects located at home? Explain.

(17-8) What is a Eurodollar? If a French citizen deposits $10,000 in Chase Bank in New York, have Eurodollars been created? What if the deposit is made in Barclays Bank in London? Chase's Paris branch? Does the existence of the Eurodollar market make the Federal Reserve's job of controlling U.S. interest rates easier or more difficult? Explain.

(17-9) Does interest rate parity imply that interest rates are the same in all countries?

(17-10) Why might purchasing power parity fail to hold?

SELF-TEST PROBLEM

Solution Shown in Appendix A

(ST-1) Cross Rates Suppose the exchange rate between U.S. dollars and euros is €0.98 = $1.00 and the exchange rate between the U.S. dollar and the Canadian dollar is $1.00 = C$1.50. What is the cross rate of euros to Canadian dollars?

PROBLEMS

Answers Are in Appendix B

EASY PROBLEMS 1–4

(17-1) Cross Rates At today's spot exchange rates 1 U.S. dollar can be exchanged for 9 Mexican pesos or for 111.23 Japanese yen. You have pesos that you would like to exchange for yen. What is the cross rate between the yen and the peso; that is, how many yen would you receive for every peso exchanged?

(17-2) Interest Rate Parity The nominal yield on 6-month T-bills is 7%, while default-free Japanese bonds that mature in 6 months have a nominal rate of 5.5%. In the spot exchange market, 1 yen equals $0.009. If interest rate parity holds, what is the 6-month forward exchange rate?

(17-3) Purchasing Power Parity A computer costs $500 in the United States. The same model costs 550 euros in France. If purchasing power parity holds, what is the spot exchange rate between the euro and the dollar?

(17-4) Exchange Rate If euros sell for $1.50 (U.S.) per euro, what should dollars sell for in euros per dollar?

INTERMEDIATE PROBLEMS 5–8

(17-5) Currency Appreciation Suppose that the exchange rate is 0.60 dollars per Swiss franc. If the franc appreciates 10% against the dollar, how many francs would a dollar buy tomorrow?

(17-6) Cross Rates Suppose the exchange rate between U.S. dollars and the Swiss franc is SFr1.6 = $1 and the exchange rate between the dollar and the British pound is £1 = $1.50. What then is the cross rate between francs and pounds?

(17-7) Interest Rate Parity Assume that interest rate parity holds. In both the spot market and the 90-day forward market, 1 Japanese yen equals 0.0086 dollar. In Japan, 90-day risk-free securities yield 4.6%. What is the yield on 90-day risk-free securities in the United States?

(17-8) Purchasing Power Parity In the spot market, 7.8 pesos can be exchanged for 1 U.S. dollar. A pair of headphones costs $15 in the United States. If purchasing power parity holds, what should be the price of the same headphones in Mexico?

CHALLENGING PROBLEMS 9–14

(17-9) Exchange Gains and Losses Your Boston-headquartered manufacturing company, Wruck Enterprises, obtained a 50-million-peso loan from a Mexico City bank last month to fund the expansion of your Monterrey, Mexico, plant. The exchange rate was 10 U.S. cents per peso when you took out the loan, but since then the exchange rate has dropped to 9 U.S. cents per peso. Has Wruck Enterprises made a gain or a loss due to the exchange rate change, and how much? Note that your shareholders live in the United States.

(17-10) Results of Exchange Rate Changes

In 1983, the Japanese yen-U.S. dollar exchange rate was 245 yen per dollar, and the dollar cost of a compact Japanese-manufactured car was $8,000. Suppose that now the exchange rate is 80 yen per dollar. Assume there has been no inflation in the yen cost of an automobile so that all price changes are due to exchange rate changes. What would the dollar price of the car be now, assuming the car's price changes only with exchange rates?

(17-11) Spot and Forward Rates

Boisjoly Watch Imports has agreed to purchase 15,000 Swiss watches for 1 million francs at today's spot rate. The firm's financial manager, James Desreumaux, has noted the following current spot and forward rates:

	U.S. Dollar/Swiss Franc	Swiss Franc/U.S. Dollar
Spot	1.6590	0.6028
30-day forward	1.6540	0.6046
90-day forward	1.6460	0.6075
180-day forward	1.6400	0.6098

On the same day, Desreumaux agrees to purchase 15,000 more watches in 3 months at the same price of 1 million Swiss francs.

a. What is the cost of the watches in U.S. dollars, if purchased at today's spot rate?
b. What is the cost in dollars of the second 15,000 batch if payment is made in 90 days and the spot rate at that time equals today's 90-day forward rate?
c. If the exchange rate for is 0.50 Swiss francs per dollar in 90 days, how much will Desreumaux have to pay (in dollars) for the watches?

(17-12) Interest Rate Parity

Assume that interest rate parity holds and that 90-day risk-free securities yield 5% in the United States and 5.3% in Germany. In the spot market, 1 euro equals $1.40. What is the 90-day forward rate? Is the 90-day forward rate trading at a premium or a discount relative to the spot rate?

(17-13) Foreign Investment Analysis

Chapman Inc.'s Mexican subsidiary, V. Gomez Corporation, is expected to pay to Chapman 50 pesos in dividends in 1 year after all foreign and U.S. taxes have been subtracted. The exchange rate in 1 year is expected to be 0.10 dollars per peso. After this, the peso is expected to depreciate against the dollar at a rate of 4% a year forever due to the different inflation rates in the United States and Mexico. The peso-denominated dividend is expected to grow at a rate of 8% a year indefinitely. Chapman owns 10 million shares of V. Gomez. What is the present value of the dividend stream, in dollars, assuming V. Gomez's cost of equity is 13%?

(17-14) Foreign Capital Budgeting

The South Korean multinational manufacturing firm, Nam Sung Industries, is debating whether to invest in a 2-year project in the United States. The project's expected dollar cash flows consist of an initial investment of $1 million with cash inflows of $700,000 in Year 1 and $600,000 in Year 2. The risk-adjusted cost of capital for this project is 13%. The current exchange rate is 1,050 won per U.S. dollar. Risk-free interest rates in the United States and S. Korea are:

	1-year	2-year
U.S.	4.0%	4.25%
S. Korea	3.0%	3.25%

a. If this project were instead undertaken by a similar U.S.-based company with the same risk-adjusted cost of capital, what would be the net present value and rate of return generated by this project?

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

b. What is the expected forward exchange rate 1 year from now and 2 years from now? (*Hint:* Take the perspective of the Korean company when identifying home and foreign currencies and direct quotes of exchange rates.)
c. If Nam Sung undertakes the project, what is the net present value and rate of return of the project for Nam Sung?

SPREADSHEET PROBLEM

(17-15)
Build a Model: Multinational Financial Management

resource

Start with the partial model in the file ***Ch17 P15 Build a Model.xlsx*** on the textbook's Web site. Mark Collins, luthier and businessman, builds and sells custom-made acoustic and electric stringed instruments. Although located in Maryville, Tennessee, he purchases raw materials from around the globe. For example, he constructs his top-of-the line acoustic guitar with onboard electronics, the MC-28, from rosewood and mahogany imported from a distributor in Mexico, spruce harvested in and imported from Canada, and ebony and the electronics imported from a Japanese distributor. He obtains other parts in the United States. When broken down on a per-guitar basis, the component and finishing costs are as follows:

Rosewood and mahogany: 2,750 Mexican pesos
Spruce: 200 Canadian dollars
Ebony and electronics: 12,400 Japanese yen
Other parts plus woodworking labor: $600

Collins sells some of this model in the United States, but the majority of the units are sold in England, where he has developed a loyal following and the guitars have become something of a cult symbol. There, his guitars fetch £1,600, excluding shipping. Mark is concerned about the effect of exchange rates on his materials costs and profit.

You will find Tables 17-1 and 17-2 useful for this problem.

a. How much, in dollars, does it cost for Collins to produce his MC-28? What is the dollar sale price of the MC-28 sold in England?
b. What is the dollar profit that Collins makes on the sale of the MC-28? What is the percentage profit?
c. If the U.S. dollar were to depreciate by 10% against all foreign currencies, what would be the dollar profit for the MC-28?
d. If the U.S. dollar were to depreciate by 10% only against the pound and remain constant relative to all other foreign currencies, what would be the dollar and percentage profits for the MC-28?
e. The rate of return on 90-day U.S. Treasury securities is 3.9% and the rate of return on 90-day U.K. risk-free securities is 5.0%. Using the spot exchange information from Table 17-1, estimate the 90-day forward exchange rate.
f. Assuming that purchasing power parity (PPP) holds, what would be the sale price of the MC-28 if it were sold in France rather than in England? (*Hint:* Assume England is the home country.)

MINI CASE

With the growth in demand for exotic foods, Possum Products's CEO Michael Munger is considering expanding the geographic footprint of its line of dried and smoked low-fat opossum, ostrich, and venison jerky snack packs. Historically, jerky products have performed well in the southern United States, but there are indications of a growing

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

demand for these unusual delicacies in Europe. Munger recognizes that the expansion carries some risk. Europeans may not be as accepting of opossum jerky as initial research suggests, so the expansion will proceed in steps. The first step will be to set up sales subsidiaries in France and Sweden (the two countries with the highest indicated demand), and the second is to set up a production plant in France with the ultimate goal of product distribution throughout Europe.

Possum Products's CFO, Kevin Uram, although enthusiastic about the plan, is nonetheless concerned about how an international expansion and the additional risk that entails will affect the firm's financial management process. He has asked you, the firm's most recently hired financial analyst, to develop a 1-hour tutorial package that explains the basics of multinational financial management. The tutorial will be presented at the next board of directors meeting. To get you started, Uram has supplied you with the following list of questions:

a. What is a multinational corporation? Why do firms expand into other countries?
b. What are the six major factors that distinguish multinational financial management from financial management as practiced by a purely domestic firm?
c. Consider the following illustrative exchange rates.

	U.S. Dollars Required to Buy One Unit of Foreign Currency	Units of Foreign Currency Required to Buy One U.S. Dollar
Euro	1.2500	–
Swedish krona	–	7.0000

(1) What is a direct quotation? What is the direct quote for euros?
(2) What is an indirect quotation? What is the indirect quotation for kronor (the plural of krona is kronor)?
(3) The euro and British pound usually are quoted as direct quotes. Most other currencies are quoted as indirect quotes. How would you calculate the indirect quote for a euro? How would you calculate the direct quote for a krona?
(4) What is a cross rate? Calculate the two cross rates between euros and kronor.
(5) Assume Possum Products can produce a package of jerky and ship it to France for $1.75. If the firm wants a 50% markup on the product, what should the jerky sell for in France?
(6) Now assume that Possum Products begins producing the same package of jerky in France. The product costs 2 euros to produce and ship to Sweden, where it can be sold for 20 kronor. What is the dollar profit on the sale?
(7) What is exchange rate risk?

d. Briefly describe the current international monetary system. How does the current system differ from the system that was in place prior to August 1971?
e. What is a convertible currency? What problems arise when a multinational company operates in a country whose currency is not convertible?
f. What is the difference between spot rates and forward rates? When is the forward rate at a premium to the spot rate? At a discount?
g. What is interest rate parity? Currently, you can exchange 1 euro for 1.25 dollars in the 180-day forward market, and the risk-free rate on 180-day securities is 6% in the United States and 4% in France. Does interest rate parity hold? If not, which securities offer the highest expected return?

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

h. What is purchasing power parity? If a package of jerky costs $2 in the United States and purchasing power parity holds, what should be the price of the jerky package in France?
i. What effect does relative inflation have on interest rates and exchange rates?
j. Briefly discuss the international capital markets.
k. To what extent do average capital structures vary across different countries?
l. Briefly describe special problems that occur in multinational capital budgeting, and describe the process for evaluating a foreign project. Now consider the following project: A U.S. company has the opportunity to lease a manufacturing facility in Japan for 2 years. The company must spend ¥1 billion initially to refurbish the plant. The expected net cash flows from the plant for the next 2 years, in millions, are CF_1 = ¥500 and CF_2 = ¥800. A similar project in the United States would have a risk-adjusted cost of capital of 10%. In the United States, a 1-year government bond pays 2% interest and a 2-year bond pays 2.8%. In Japan, a 1-year bond pays 0.05% and a 2-year bond pays 0.26%. What is the project's NPV?
m. Briefly discuss special factors associated with the following areas of multinational working capital management:

(1) Cash management
(2) Credit management
(3) Inventory management

CHAPTER 18

Public and Private Financing: Initial Offerings, Seasoned Offerings, and Investment Banks

On May 18, 2012, Facebook went public in one of the most eagerly anticipated initial public offerings (IPO) of the decade. Facebook and some of its founders/investors sold about 421 million shares for $38 each, but subsequent trading on NASDAQ was delayed for 30 minutes due to technological problems. When trading did begin, the price quickly went up to over $42. Although the price rose to $45 during the day, most new investors were selling the stock, putting downward pressure on the price. Morgan Stanley, one of the underwriters, kept the price from plunging by purchasing enough shares itself to create artificial demand. By the end of the day, the price was down to $38.23, barely above the initial price. During the following two weeks, the price fell below $26, and finger pointing and blaming ensued.

First, analysts and investors complained that shortly before its IPO, Facebook had increased the number of shares it planned to sell and then sold them at a higher-than-expected price. This combination, they said, reduced demand for the stock and hurt the per share value.

Second, there was pandemonium during the day when traders were unable to confirm their trades. For example, UBS (a large Swiss financial institution) claimed it suffered $350 million in losses due to the interruption in information. NASDAQ offered $40 million in compensation to brokerage firms that lost money due to the information interruption, but that is unlikely to satisfy all the traders.

Third, some investors sued Facebook and its underwriters, alleging that they concealed a reduction in projected sales revenues from all but a few favored clients.

We will have more to say about Facebook's IPO later in the chapter, so keep these events in mind.

Previous chapters described how a company selects projects, chooses its capital structure, and implements its dividend policy. These activities determine the amount of new capital a company must raise and the debt/equity mix of that new capital. In this chapter, we describe the actual process of raising capital from the public markets (such as selling stock in an initial public offering) and private markets (such as selling stock to a private investor like a pension fund). We also describe the roles investment banks and regulatory agencies play in raising capital.

18-1 The Financial Life Cycle of a Start-Up Company

Most businesses begin life as proprietorships or partnerships, and if they become successful and grow, at some point they find it desirable to become corporations. Initially, most corporate stock is owned by the firms' founding managers and key employees. Even start-up firms that are ultimately successful usually begin with negative free cash flows because of their high growth rates and product development costs; hence, they must raise capital during these high-growth years. If the founding owner-managers have invested all of their own financial resources in the company, then they must turn to outside sources of capital. Start-up firms generally have high growth opportunities, and they suffer from especially large problems due to asymmetric information. Therefore, as we discussed in Chapter 15, they must raise external capital primarily as equity rather than debt.

To protect investors from fraudulent stock issues, in 1933 Congress enacted the Securities Act, which created the **Securities and Exchange Commission (SEC)** to regulate the financial markets.[1] The Securities Act regulates interstate public offerings, which we explain later in this section, but it also provides several exemptions that allow companies to issue securities through **private placements** that are not registered with the SEC. The rules governing these exemptions are quite complex, but in general they restrict the number and type of investors who may participate in an issue. **Accredited investors** include the officers and directors of the company, high-wealth individuals, and institutional investors. In a nonregistered private placement, the company may issue securities to an unlimited number of accredited investors but to only 35 nonaccredited investors. In addition, none of the investors can sell their securities in the secondary market to the general public.

For most start-ups, the first round of external financing comes through a private placement of equity to one or two individual investors, called **angel investors**. In return for a typical investment in the range of $50,000 to $400,000, the angels receive stock and perhaps also a seat on the board of directors. Because angels can influence the strategic direction of the company, it is best when they bring experience and industry contacts to the table in addition to cash.

As the company grows, its financing requirements may exceed the resources of individual investors, in which case it is likely to turn to a **venture capital fund**. A venture capital fund is a private limited partnership, which typically raises $30 million to $80 million from a relatively small group of primarily institutional investors, including

[1] In addition to federal statutes, which affect transactions that cross state borders, states have "blue sky" laws that regulate securities sold just within the state. These laws were designed to prevent unscrupulous dealers from selling something of little worth, such as the blue sky, to naïve investors.

pension funds, college endowments, and corporations.[2] The managers of a venture capital fund, called **venture capitalists**, or **VCs**, are usually very knowledgeable and experienced in a particular industry, such as health care or biotechnology. They screen hundreds of companies and ultimately fund around a dozen, called **portfolio companies**. The venture fund buys shares of the portfolio companies, and the VCs sit on the companies' boards of directors. The venture capital fund usually has a prespecified life of 7 to 10 years, after which it is dissolved, either by selling the portfolio companies' stock and distributing the proceeds to the funds' investors or by directly distributing the stock to the investors.

What is an angel investor?

What is a venture capital fund? A VC?

18-2 The Decision to Go Public

Going public means selling some of a company's stock to outside investors in an initial public offering (IPO) and then letting the stock trade in public markets. For example, the babysitting, nanny, and eldercare company Care.com, the performance boat manufacturer Malibu Boats, the financial services company Ally Financial, and the online takeout food ordering portal Grubhub.com all went public in 2014. There are advantages and disadvantages for going public, as explained next.

18-2a Advantages of Going Public

The advantages to going public include the following:

1. *Increases liquidity and allows founders to harvest their wealth.* The stock of a private, or closely held, corporation is illiquid. It may be hard for one of the owners who wants to sell some shares to find a ready buyer, and even if a buyer is located, there is no established price on which to base the transaction.
2. *Permits founders to diversify.* As a company grows and becomes more valuable, its founders often have most of their wealth tied up in the company. By selling some of their stock in a public offering, they can diversify their holdings, thereby reducing the riskiness of their personal portfolios.
3. *Facilitates raising new corporate cash.* If a privately held company wants to raise cash by selling new stock, it must either go to its existing owners, who may not have any money or may not want to put more eggs in this particular basket, or else shop around for wealthy investors. However, it is usually quite difficult to get outsiders to put money into a closely held company: If the outsiders do not have voting control (more than 50% of the stock), then the inside stockholders/managers can take advantage of them. Going public, which brings with it both public disclosure of information and regulation by the SEC, greatly reduces this problem and thus

[2]The typical venture capital fund is a private limited partnership, with limited partners and a general partner. The limited partners contribute cash but are prohibited from being involved in the partnership's decision making. Because of their limited participation, they are not held liable for any of the partnership's liabilities, except to the extent of their original investment. The general partner usually contributes a relatively modest amount of cash but acts as the partnership's manager. In return, the general partner normally receives annual compensation equal to 1% to 2% of the fund's assets plus a 20% share of the fund's eventual profits.

makes people more willing to invest in the company, which makes it easier for the firm to raise capital.

4. *Establishes a value for the firm.* If a company wants to give incentive stock options to key employees, it is useful to know the exact value of those options. Employees much prefer to own stock, or options on stock, that is publicly traded and therefore liquid. Also, when the owner of a privately owned business dies, state and federal tax appraisers must set a value on the company for estate tax purposes. Often these appraisers set a higher value than that of a similar publicly traded company.
5. *Facilitates merger negotiations.* Having an established market price helps when a company either is being acquired or is seeking to acquire another company in which the payment will be with stock.
6. *Increases potential markets.* Many companies report that it is easier to sell their products and services to potential customers after they become publicly traded.

18-2b Disadvantages of Going Public

The disadvantages associated with going public include the following.

1. *Increases reporting costs.* A publicly owned company must file quarterly and annual reports with the SEC and/or various state agencies. These reports can be a costly burden, especially for small firms. In addition, compliance with the Sarbanes-Oxley Act often requires considerable expense and manpower.
2. *Increases disclosure requirements.* Management may not like the idea of reporting operating data, because these data will then be available to competitors. Similarly, the owners of the company may not want people to know their net worth. But because a publicly owned company must disclose the number of shares its officers, directors, and major stockholders own, it is easy enough for anyone to multiply shares held by price per share to estimate the net worth of the insiders.
3. *Increases risk of having an inactive market and/or low price.* If the firm is very small and if its shares are not traded frequently, then its stock will not really be liquid and so the market price may not represent the stock's true value. Security analysts and stockbrokers simply will not follow the stock, because there will not be sufficient trading activity to generate enough brokerage commissions to cover the costs of following it.
4. *Reduces owner/manager control.* Because of possible tender offers and proxy fights, the managers of publicly owned firms who do not have voting control must be concerned about maintaining control. Further, there is pressure on such managers to produce annual earnings gains, even when it might be in the shareholders' best long-term interests to adopt a strategy that reduces short-term earnings but raises them in future years. These factors have led a number of public companies to "go private" in leveraged buyout deals, where the managers borrow the money to buy out the nonmanagement stockholders. We discuss the decision to go private in a later section.
5. *Increases time spent on investor relations.* Public companies must keep investors abreast of current developments. Many CFOs of newly public firms report that they spend 2 full days a week talking with investors and analysts.

18-3 The Process of Going Public: An Initial Public Offering

An initial public offering is complicated, expensive, and time-consuming, as the following explains.

18-3a Selecting an Investment Bank

After a company decides to go public, it faces the problem of how to sell its stock to a large number of investors. Although most companies know how to sell their products, few have experience in selling securities. To help in this process, the company will interview a number of different **investment banks**, also called **underwriters**, and then select one to be the lead underwriter. To understand the factors that affect this choice, it helps to understand exactly what investment banks do in an IPO.

First, the investment bank helps the firm determine the preliminary offering price, or price range, for the stock and the number of shares to be sold. The investment bank's reputation and experience in the company's industry are critical in convincing potential investors to purchase the stock at the offering price. In effect, the investment bank implicitly certifies that the stock is not overpriced, which obviously comforts investors. Second, the investment bank actually sells the shares to its existing clients, which include a mix of institutional investors and retail (that is, individual) customers. Third, the investment bank, through its associated brokerage house, will have an analyst "cover" the stock after it is issued. This analyst will regularly distribute reports to investors describing the stock's prospects, which will help to maintain an interest in the stock. Well-respected analysts increase the likelihood that there will be a liquid secondary market for the stock and that its price will reflect the company's true value.

Some activities in finance involve as much marketing skill as finance expertise. For example, the selection of an underwriter often is described as a bake-off in which the competing investment banks woo the company with their best sales pitch, much like a cake-baking contest in which bakers vie for first prize.

Facebook chose Morgan Stanley to be its lead underwriter, but other investment banks were also involved, as we explain next.

18-3b The Underwriting Syndicate

The firm and its investment bank must next decide whether the bank will work on a **best efforts basis** or will **underwrite** the issue. In a best efforts sale, the bank does not guarantee that the securities will be sold or that the company will get the cash it needs, only that it will put forth its "best efforts" to sell the issue. On an underwritten issue, in contrast, the company does get a guarantee: The bank agrees to buy the entire issue and then resell the stock to its customers. Therefore, the bank bears significant risks in underwritten offerings.

Except for extremely small issues, virtually all IPOs are underwritten. Investors are required to pay for securities within 10 days, and the investment bank must pay the issuing firm within 4 days of the official commencement of the offering. Typically, the bank sells the stock within a day or two after the offering begins, but on occasion the bank miscalculates, sets the offering price too high, and thus is unable to move the issue. At other times, the market declines during the offering period, forcing the bank to reduce the price of the stock or bonds. In either instance, on an underwritten offering the firm receives the price that was agreed upon, so the bank must absorb any losses that are incurred.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Because they are exposed to large potential losses, investment banks typically do not handle the purchase and distribution of issues single-handedly unless the issue is very small. If the sum of money involved is large, then investment banks form **underwriting syndicates** in an effort to minimize the risk each individual bank faces. The banking house that sets up the deal is called the **lead underwriter** or the **managing underwriter**. Syndicated offerings are usually covered by more analysts, which contribute to greater liquidity in the post-IPO secondary market. Thus, syndication provides benefits to both underwriters and issuers.

In addition to the underwriting syndicate, on larger offerings still more investment banks are included in a **selling group**, which handles the distribution of securities to individual investors. The selling group includes all members of the underwriting syndicate plus additional dealers who take relatively small percentages of the total issue from the members of the underwriting syndicate. Thus, the underwriters act as wholesalers while members of the selling group act as retailers. The number of brokerage houses in a selling group depends partly on the size of the issue, but it is normally in the range of 10 to 15.

In addition to Morgan Stanley, Facebook's underwriting and sales syndicate included over 30 firms, including Goldman Sachs, Merrill Lynch, Barclays, Citigroup, Credit Suisse Securities, Deutsche Bank Securities, and Wells Fargo.

A new selling procedure has recently emerged that takes advantage of the trend toward institutional ownership of stock. In this type of sale, called an **unsyndicated stock offering**, the managing underwriter—acting alone—sells the issue entirely to a group of institutional investors, thus bypassing both retail stockbrokers and individual investors. In recent years, about 50% of all stock sold has been by unsyndicated offerings. Behind this phenomenon is a simple motivating force: money. The fees that issuers pay on a syndicated offering, which include commissions paid to retail brokers, can run a full percentage point higher than those on unsyndicated offerings. Moreover, although total fees are lower in unsyndicated offerings, managing underwriters usually come out ahead because they do not have to share the fees with an underwriting syndicate. However, some types of stock do not appeal to institutional investors, so not all firms can use unsyndicated offers.

18-3c Regulation of Securities Sales

WWW

The SEC Web site allows users to search for any filings by a company, including Form S-1. See **www.sec.gov/edgar.shtml**.

Sales of new securities, and also sales in the secondary markets, are regulated by the Securities and Exchange Commission and, to a lesser extent, by each of the 50 states. There are four primary elements of SEC regulation.

1. *Jurisdiction.* The SEC has jurisdiction over all **interstate public offerings** in amounts of $1.5 million or more.
2. *Registration.* Newly issued securities (stocks and bonds) must be registered with the SEC at least 20 days before they are publicly offered. The **registration statement**, called Form S-1, provides financial, legal, and technical information about the company to the SEC. A **prospectus**, which is embedded in the S-1, summarizes this information for investors. The SEC's lawyers and accountants analyze both the registration statement and the prospectus; if the information is inadequate or misleading, the SEC will delay or stop the public offering.[3]

[3]It is easy to obtain the S-1 form, which typically has 50 to 200 pages of financial statements in addition to a detailed discussion of the firm's business, the risks and opportunities the firm faces, its principal stockholders and managers, what will be done with the funds raised, and the like. The company seeking to go public files the statement with the SEC, which makes it immediately available to investors via the Internet. The SEC staff reviews the filed S-1, and amendments may be issued (labeled S-1/A). The likely range for the offering price will be reported—for example, $13 to $15 per share. If the market strengthens or weakens during the SEC review, the price may be increased or decreased right up until the last day. The SEC Web site for these and other filings is **www.sec.gov**.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Among its disclosures, the S-1 document and subsequent amendments (S-1/A) show the proposed number of shares to be sold (including a breakdown between shares sold by the company and shares sold by current stockholders, including the founders and investors) and a range of possible offering prices (the prices at which the first investors may purchase the stock). For example, Facebook's S-1 filing on February 1, 2012, did not specify either the number of shares or price range, but its amended statement on May 3, 2012, stated that Facebook would offer 337 million shares (180 million from the company and 157 million shares from its current stockholders) at a price between $28 and $35 per shares.

3. *Prospectus.* After the SEC declares the registration to be effective, new securities may be advertised, but all sales solicitations must be accompanied by the prospectus. **Preliminary prospectuses**, which are also called **"red herring" prospectuses**, may be distributed to potential buyers during the 20-day waiting period after the registration is effective, but no sales may be finalized during this time. The "red herring" prospectus (so called because it has a standard legal disclaimer printed in red across its cover) contains all the key information that will appear in the final prospectus except the final price, which is generally set after the market closes the day before the new securities are offered to the public.
4. *Truth in reporting.* If the registration statement or prospectus contains misrepresentations or omissions of material facts, then any purchaser who suffers a loss may sue for damages. Severe penalties may be imposed on the issuer or its officers, directors, accountants, engineers, appraisers, underwriters, and all others who participated in the preparation of the registration statement or prospectus.

18-3d The Roadshow and Book-Building

After the registration statement has been filed, the senior management team, the investment banker, and the company's lawyers go on a **roadshow**. The management team will make three to seven presentations each day to potential institutional investors, who typically are existing clients of the underwriters. The institutional investors ask questions during the presentation, but the management team may not give any information that is not in the registration statement. Nor may the management team make any forecasts or express any opinions about the value of their company. These provisions are due to the SEC-mandated **quiet period**. This quiet period begins when the registration statement is made effective and lasts for 40 days after the stock begins trading. Its purpose is to create a level playing field for all investors by ensuring that they all have access to the same information. It is not uncommon for the SEC to delay an IPO if managers violate the quiet period rules. The typical roadshow may last 10 to 14 days, with stops in 10 to 20 different cities. In many ways the process resembles a coming-out party for the company, but it is more grueling and has much higher stakes.

After each presentation, the investment banker asks the investor for an indication of interest based on the offering price range shown in the registration statement. The investment banker records the number of shares each investor is willing to buy, which is called **book-building**. As the roadshow progresses, an investment bank's "book" shows how demand for the offering is building. Many IPOs are **oversubscribed**, with investors wishing to purchase more shares than are available. In such a case, the investment bank will allocate shares to the investors on a pro rata basis.[4] If demand is

[4]Most underwriting agreements contain an "overallotment option" that permits the underwriter to purchase additional shares from the company, up to 15% of the issue size, to cover promises made to potential buyers. This is called a "green shoe" agreement because it was first used in the 1963 underwriting of a company named Green Shoe.

high enough, the banks may increase the offering price; if demand is low, they will either reduce the offering price or withdraw the IPO. Sometimes low demand is specifically due to concern over the company's future prospects, but sometimes low demand is caused by a fall in the general stock market. Thus, the timing of the roadshow and offering date are important. As the old saying goes, sometimes it is better to be lucky than good.

18-3e Setting the Offer Price

Before trading can begin, a company must file a final amended registration statement showing the actual number of shares to be sold and the final price range. A company usually announces the actual **offer price** the day before the IPO. This is the price at which the investment banking syndicate sells stocks to the buyers it lined up during the road-show. The investment bank then pays these proceeds to the issuing company, less a percentage that is called the underwriting spread (we discuss all the costs of an IPO in following sections).

How do the company and its investment bankers set the offering price? It is simple in theory but complicated in practice, so we will start with theory. There are two situations: (1) A company knows how many shares it plans to sell. (2) It knows how much cash it needs to raise.

SETTING THE OFFER PRICE IF THE NUMBER OF NEW SHARES IS KNOWN

A company must decide how much ownership it wishes to sell to new investors, and this depends on the number of shares owned by the founder and previous investors, $n_{Existing}$, and the number of new shares purchased by new investors, n_{New}:

$$\text{Percentage shares owned by new investors} = \frac{n_{New}}{n_{New} + n_{Existing}} \quad \textbf{(18-1)}$$

Given the target percentage to be sold, Equation 18-1 can be solved for the required number of new shares to sell:

$$n_{New} = \frac{(\%\ \text{owned by new investors})n_{Existing}}{1 - (\%\ \text{owned by new investors})} \quad \textbf{(18-1a)}$$

The company and investment banker must estimate the value of the company and the value of its equity prior to the IPO, $V_{Pre\text{-}IPO}$. The total value of equity after the IPO is the sum of the pre-IPO value and the proceeds from the IPO, net of the underwriter's spread. Letting P_{Offer} denote the offer price, and F denote the percentage spread, the post-IPO value of equity, $V_{Post\text{-}IPO}$, is:

$$V_{Post\text{-}IPO} = V_{Pre\text{-}IPO} + P_{Offer}(1 - F)n_{New} \quad \textbf{(18-2)}$$

The new investors will buy stock only if their stake after the IPO is at least as big as the amount they pay for the shares. Their stake is equal to the post-IPO value of the company multiplied by the percentage of the company that they own, and the amount they pay is

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

equal to the offer price multiplied by the number of new shares. Using this observation, Equations 18-1, 18-2, and considerable algebra, we get:

$$P_{Offer} = \left[\frac{V_{Pre\text{-}IPO}}{F(n_{New}) + n_{Existing}}\right] \quad \textbf{(18-3)}$$

For example, Facebook's founders and early investors owned 1.96 billion shares before the IPO and Facebook sold 0.18 billion new shares in the IPO. If the pre-IPO value of Facebook was $75 billion and the investment bank's spread was 7%, the offer price should have been:

$$P_{Offer} = \left[\frac{\$75}{(0.07)(0.18) + 1.96}\right] = \$38.02$$

After a company announces the offer price, analysts can use Equation 18-3 to solve for the pre-IPO value implied by the pricing, which is what we did for the example using Facebook. After the investment banker's spread, Facebook's proceeds were about $\$38.02(1 - 0.07)(0.18 \text{ billion}) = \$6.4$ billion. The new investors owned about 8.4% of Facebook: $0.18/(0.18 + 1.96) = 8.4\%$.

SETTING THE OFFER PRICE IF THE TARGET PROCEEDS ARE KNOWN

How does a company set the offer price if it needs a certain amount of proceeds? The basic idea is to determine the ratio of the value of the investment by new investors to the post-IPO value. From the new investors' perspectives, this is the percentage of ownership they must have to justify their investment. The post-IPO value is equal to the pre-IPO value plus the net proceeds, so the percentage ownership required by new investors is:

$$\%\text{ of shares required by new investors} = \frac{\text{Investment}}{(1 - F)\text{Investment} + V_{Pre\text{-}IPO}} \quad \textbf{(18-4)}$$

For example, suppose a company has a pre-IPO value of $50 million, has 2 million existing shares, needs $9.3 million in net proceeds, and the investment bank charges a 7% spread. The company must sell $10 million of stock to investors in order to net the desired $9.3 million: $(\$10 \text{ million})(1 - 0.07) = \$9.3$ million. Using Equation 18-4, the new investors will require a 16.86% stake in the company:

$$\%\text{ of shares required by new investors} = \frac{\$10}{(1 - 0.07)\$10 + \$50} = 16.86\%$$

Equation 18-1a can be used to solve for the number of new shares:

$$n_{New} = \frac{(0.1686)(2{,}000{,}000)}{(1 - 0.1686)} = 405{,}581$$

The price per share is found by dividing the investment by the number of new shares: $\$10{,}000{,}000/405{,}581 = \$24.656 \approx \$24.65$.

A quicker way to make this calculation is to recognize that the existing shareholders bear the underwriting cost because the new investors must receive stock exactly equal to their cost. For this example, the underwriting cost is $0.07(\$10 \text{ million}) = \$0.7$ million. Subtracting this from the pre-IPO value and dividing by the existing number of shares

gives the same price of \$24.65 = (\$10 − \$0.07)/2. After calculating the IPO price of \$24.65, it is a simple matter to find the number of new shares by dividing the investment of \$10 million by the price per share: \$10,000,000/\$24.65 = 405,680 shares, the same as we found previously, except for rounding differences.

CONFLICTS BETWEEN THE COMPANY AND THE INVESTMENT BANK

Although the pricing is simple in theory, there are big conflicts of interest in practice. The issuing company wants the offer price to be high because that will generate more cash in the IPO or reduce the number of shares that must be sold. However, the investment banker in an underwritten IPO is afraid of being stuck with overvalued stock if the offer price is too high. Although rare, some IPOs have been canceled at the last moment because the company and the underwriters could not reach an agreement.

18-3f The First Day of Trading

The first day of trading for many IPOs can be wild and exciting. Table 18-1 shows the largest first-day returns for IPOs during 2013. Some stocks end the day with large gains, such as the 123% price increase of Sprouts Farmers Market, as shown in Line 1 of the table. Others have a sharp run-up and then fall back by the end of the day. A few IPOs actually end their first day with a loss. Professor Jay Ritter of the University of Florida reported that the average first-day return in 2014 was about 15.5%, a bit lower than the 1980–2014 return of 18.0%.[5]

In one of the most famous IPOs of the decade, Facebook broke even on the first day, May 18, 2012, and would have fallen if the underwriters had not created artificial demand by purchasing the falling shares. On the second day, Facebook fell by 11%. Facebook's amended filings in the week before its IPO may have contributed to its weak first-day performance. On May 15, 2012, Facebook filed an amended S-1/A increasing the range of

TABLE 18-1
Highest First-Day IPO Returns in 2013

Rank	Company	Offering Price	First-Day Closing Price	Gain
1	Sprouts Farmers Market	\$18.00	\$40.11	123%
2	Noodles & Company	\$18.00	\$36.75	104%
3	Benefitfocus	\$26.50	\$53.55	102%
4	The Container Store Group	\$18.00	\$36.20	101%
5	Foundation Medicine	\$18.00	\$35.35	96%
6	Rocket Fuel Inc.	\$29.00	\$56.10	93%
7	China Commercial Credit	\$ 6.50	\$12.45	92%
8	Qunar Cayman Islands Limited	\$15.00	\$28.40	89%
9	FireEye	\$20.00	\$36.00	80%
10	Marketo	\$13.00	\$23.10	78%

prices from $28–$35 to $34–$38. On May 16, Facebook filed another amendment increasing by 84 million shares the amount to be sold by insiders. On May 17, Facebook announced that the offer price would be $38 per share, at the very top of the already higher range. Facebook's stock began trading the next day.

Many analysts were surprised by these increases in the offer price and the number of shares to be sold, especially the proportion of shares from insiders, which rose to 57% of the total sold in the IPO. To put this in perspective, Google's insiders represented about 28% of its IPO, but some insiders don't sell any of their shares in an IPO, like the insiders at Amazon in 1994. It is possible that this increase in supply and cost drove down demand for the stock.

According to a study of IPOs during 1990–1998 by Professors Tim Loughran and Jay Ritter, about 27.3% of the IPOs had an offer price that was lower than the low range in their initial registration filing, and these stocks had an average first-day return of 4.0%.[6] Even though the average return was positive, 47% of these stocks actually ended the day with a loss or no gain. About 48.4% of IPOs had an offering price that was within the range of their initial filing. For such companies, the average first-day return was 10.8%. As a result of high demand during the roadshow, 24.3% of IPOs had a final offer price that exceeded their original range. These stocks had an average first-day return of 31.9%. Overall, the average first-day return was 14.1% during 1990–1998, with 75% of all IPOs having a positive return. During 1999, the average first-day return was an astronomical 70%!

You're probably asking yourself two questions: (1) How can I get in on these deals? (2) Why is the offering price so low? First, you probably can't get the chance to buy an IPO at its offering price, especially not a "hot" one. Virtually all sales go to institutional investors and preferred retail customers. A few Web-based investment banks are trying to change this, such as the OpenIPO of W. R. Hambrecht & Co., but right now it is difficult for small investors to get in on the first day for hot IPOs.

Various theories have been put forth to explain IPO underpricing. As long as issuing companies don't complain, investment banks have strong incentives to underprice the issue. First, underpricing increases the likelihood of oversubscription, which reduces the risk to the underwriter. Second, most investors who get to purchase the IPO at its offering price are preferred customers of the investment bank, and they became preferred customers by generating lots of commissions in the investment bank's sister brokerage company. Therefore, the IPO is an easy way for the underwriter to reward customers for past and future commissions. Third, the underwriter needs an honest indication of interest when building the book prior to the offering, and underpricing is a possible way to secure this information from the institutional investors.

But why don't issuing companies object to underpricing? Some do, and they are seeking alternative ways to issue securities, such as OpenIPO. However, most seem content to leave some money on the table. The best explanations seem to be that: (1) The company wants to create excitement, and a price run-up on the first day does that. (2) Only a small percentage of the company's stock generally is offered to the public, so current stockholders lose less to underpricing than appears at first glance. (3) IPO companies generally plan to have additional offerings in the future, and the best way to ensure future success is to have a successful IPO, which underpricing guarantees.

Although IPOs on average provide large first-day returns, their long-term returns over the following 3 years are below average. For example, if you could not get in at the IPO price but purchased a portfolio of IPO stocks on their second day of trading, your 3-year

[6]See Tim Loughran and Jay R. Ritter, "Why Don't Issuers Get Upset about Leaving Money on the Table in IPOs?" *Review of Financial Studies*, 2002, pp. 413–444.

return would have been lower than the return on a portfolio of similar but seasoned stocks. In summary, the offering price appears to be too low, but the first-day run-up is generally too high.

18-3g The Costs of Going Public

During recent years, virtually all investment banks have charged a 7% **spread** between the price they pay the issuing company and the price at which they sell shares to the public. Thus, they keep 7% of the offering price as their compensation. For example, Malibu Boats (MBUU), a manufacturer of watersport boats, went public in 2014. MBUU sold 7.642 million shares at an offering price of $14.00 to the public, while the founders and other shareholders sold an additional 571,289 of their own shares. In this IPO, the underwriters' direct compensation was $0.98 per share, which means that the stock was sold at a price of $14 to the public but MBUU received only $14.00 − $0.98 = $13.02 per share. For the 7.642 million shares issued by MBUU, these direct underwriting costs totaled about $0.98(7.642) = $7.5 million, and some $559,000 for the shares sold by the founders and other existing shareholders.

There are other direct costs as well, such as lawyers' fees, accountants' costs, printing, engraving, and so on. MBUU estimated that these fees totaled about $800,000.

Last but not least are the indirect costs. The money left on the table, which is equal to the number of shares multiplied by the difference in the closing price and the offering price, can be quite large. MBUU experienced a first-day run-up to $17.00 from an offering price of $14.00, so its indirect costs totaled 7.642($17.00 − $14.00) = $22.9 million. In addition, senior managers spend an enormous amount of time working on the IPO rather than managing the business, which certainly carries a high cost even if it cannot be easily measured.

Thus, MBUU received proceeds of 7.642($14 − $0.98) = $99.50 million, the underwriters and their sales forces received $7.5 million, other expenses totaled about $0.8 million, and $22.9 million was left on the table. There were undoubtedly other indirect costs due to the time management spent on the IPO instead of running the company. As you can see, an IPO is quite expensive.[7]

18-3h The Importance of the Secondary Market

An active secondary market after the IPO provides the pre-IPO shareholders with a chance to convert some of their wealth into cash, makes it easier for the company to raise additional capital later, makes employee stock options more attractive, and makes it easier for the company to use its stock to acquire other companies. Without an active secondary market, there would be little reason to have an IPO. Thus, companies should try to ensure that their stock will trade in an active secondary market before they incur the high costs of an IPO.

As part of the IPO process, the stock will be listed on a stock exchange, usually the NYSE or the NASDAQ. To be listed, a company must apply to an exchange, pay a relatively small fee, and meet the exchange's minimum requirements regarding net income, total market value, and "float," which is the number of shares outstanding and in the hands of outsiders (as opposed to the number held by insiders, who generally do

not actively trade their stock).[8] Also, the company must agree to disclose certain information to the exchange and to help the exchange track trading patterns and thus ensure that no one is attempting to manipulate the stock's price.

As part of its IPO duties, the investment bank (or its parent company) usually agrees to make a market in a company's stock by holding an inventory of the shares and meeting demand in the secondary market by offering to buy or sell the stock. The diligence with which it carries out this task can have a huge effect on the stock's liquidity in the secondary market and thus on the success of the IPO.

18-3i Regulating the Secondary Market

As we stated earlier, a liquid and crime-free secondary market is critical to the success of an IPO or any other publicly traded security. So, in addition to regulating the process for issuing securities, the Securities Exchange Commission also has responsibilities in the secondary markets. The primary elements of SEC regulation are set forth next.

1. *Stock exchanges.* The SEC *regulates all national stock exchanges,* and companies whose securities are listed on an exchange must file annual reports similar to the registration statement with both the SEC and the exchange.
2. *Insider trading.* The SEC has control over trading by corporate *insiders.* Officers, directors, and major stockholders must file monthly reports of changes in their holdings of the stock of the corporation. Any short-term profits from such transactions must be turned over to the corporation.
3. *Market manipulation.* The SEC has the power to *prohibit manipulation* by such devices as pools (large amounts of money used to buy or sell stocks to artificially affect prices) or wash sales (sales between members of the same group to record artificial transaction prices).
4. *Proxy statements.* The SEC has *control over the proxy statement* and the way the company uses it to solicit votes.

Control over credit used to buy securities is exercised by the Federal Reserve Board through **margin requirements**, which specify the maximum percentage of the purchase price someone can borrow. If a great deal of margin borrowing has persisted, then a decline in stock prices can result in inadequate coverages. This could force stockbrokers to issue **margin calls**, which require investors either to put up more money or have their margined stock sold to pay off their loans. Such forced sales further depress the stock market and thus can set off a downward spiral. The required "initial margin" at the time a stock is purchased has been 50% since 1974; required "maintenance margin" after the initial purchase is lower than the initial margin and is set by the individual lender.

The securities industry itself realizes the importance of stable markets, sound brokerage firms, and the absence of stock manipulation.[9] Therefore, the various exchanges work

[8]For additional discussion on the benefits of listing, see H. Kent Baker and Richard B. Edelman, "AMEX-to-NYSE Transfers, Market Microstructure, and Shareholder Wealth," *Financial Management*, Winter 1992, pp. 60–72; and Richard B. Edelman and H. Kent Baker, "Liquidity and Stock Exchange Listing," *The Financial Review*, May 1990, pp. 231–249.

[9]It is illegal for anyone to attempt to manipulate the price of a stock. During the 1920s and earlier, syndicates would buy and sell stocks back and forth at rigged prices so the public would believe that a particular stock was worth more or less than its true value. The stock exchanges, with the encouragement and support of the SEC, utilize sophisticated computer programs to help spot any irregularities that suggest manipulation, and they require disclosures to help identify manipulators. This system also helps to identify illegal insider trading. It is now illegal to manipulate a stock's price by spreading false news on the Internet.

closely with the SEC to police transactions and to maintain the integrity and credibility of the system. Similarly, the **Financial Industry Regulatory Authority (FINRA)** cooperates with the SEC to police trading and broker conduct. These industry groups also cooperate with regulatory authorities to set standards for securities firms, to develop insurance programs to protect the customers of failed brokerage houses, and provide resolution of complaints made by investors regarding brokers.

In general, government regulation of securities trading, as well as industry self-regulation, is designed to ensure that: (1) Investors receive information that is as accurate as possible. (2) No one artificially manipulates the market price of a given stock. (3) Corporate insiders do not take advantage of their position to profit in their companies' stocks at the expense of other stockholders. The SEC, the state regulators, and the industry itself can't prevent investors from making foolish decisions or from having "bad luck," but they can and do help investors obtain the best data possible for making sound investment decisions.

18-3j Questionable IPO Practices

Among the many revelations to come out during 2002 regarding investment banking was the practice by some investment banking houses of letting CEOs and other high-ranking corporate executives in on "hot" IPOs. In these deals, the demand for the new stock was far greater than supply at the offering price, so the investment banks were virtually certain that the stock would soar far above the offering price.

Some investment banks systematically allocated shares of hot IPOs to executives of companies that were issuing stocks and bonds—and thus generating fees to the banks who underwrote the deals. Bernie Ebbers, the chairman and CEO of WorldCom—one of the biggest sources of underwriting fees for investment banks—was given huge allocations in hot IPOs, and he made millions on these deals. Ebbers is just one example; a lot of this was going on in the late 1990s, at the height of the tech/dot-com bubble.

Government regulators investigated this practice, called "spinning," and corporate executives and investment bankers were charged with something that amounts to a kickback scheme under which those executives who favored particular investment banks were rewarded with allocations in hot IPOs. Indeed, in 2003 ten Wall Street securities firms agreed to pay $1.4 billion in fines to settle charges of investor abuse, including spinning. The corporate executives were paid to work for their stockholders, so they should have turned over any IPO profits to their companies—not kept those profits for themselves. This practice was found to be a form of bribery by the New York Supreme Court and was ruled to be illegal in 2006.

This kind of unethical and illegal behavior may help to explain past IPO underpricing and "money left on the table" if executives allowed their IPOs to be underpriced in exchange for allocations of similarly underpriced shares in other IPOs. Whether or not similar activities take place now remains to be seen.

In summary, we have a hard time justifying IPO underpricing during the late 1990s on rational economic grounds. Researchers and analysts have come up with explanations for why companies let their investment banks price their stocks too low in IPOs, but those reasons seem rather weak. However, when coupled with what may have been a kickback scheme, the underpricing is less puzzling (but still ethically troubling). Before closing, we should make it clear that relatively few corporate executives were corrupt. However, just as one rotten apple can spoil an entire barrel, a few bad executives—when combined with lax regulation—can help a bad practice become "the industry standard," and thus become widespread.

SELF-TEST

What is the difference between best efforts *and* underwriting?

What are some SEC regulations regarding sales of new securities?

What is a roadshow? What is book-building?

What is underpricing? What is leaving money on the table?

What are some of the costs of going public?

A privately held company has an estimated value of equity equal to $100 million. The founders own 10 million shares. If the company goes public and sells 1 million shares with no underwriting costs, how much should the per share offer price be? **($10.00)** *If instead the underwriting spread is 7%, what should the offer price be?* **($9.93)**

A company is planning an IPO. Its underwriters have said the stock will sell at $50 per share. The underwriters will charge a 7% spread. How many shares must the company sell to net $93 million, ignoring any other expenses? **(2 million)**

18-4 Equity Carve-Outs: A Special Type of IPO

In 2014, General Electric sold to the public about 15% of the equity in its wholly owned subsidiary, Synchrony Financial. In this transaction, the subsidiary, like the parent, became publicly owned, but the parent retained full control of the subsidiary by keeping about 85% of the subsidiary's common stock. (Parent companies typically retain at least 80% of the subsidiary's common stock to preserve their ability to file a consolidated tax return.) This type of transaction is called an **equity carve-out** (or **partial public offering**, or **spin-out**).[10] The market's response to Synchrony's carve-out was neutral—the stock price remained flat the first week of trading. The announcement (as opposed to the completion) of a carve-out, however, is typically associated with a stock price increase. This leads to an interesting question: Why do carve-out announcements typically result in stock price increases while the announcements of new stock issues by parent corporations generally decrease stock prices?

One possible answer is that carve-outs facilitate the evaluation of corporate growth opportunities on a line-of-business basis. Thus, analysts might have an easier time evaluating Synchrony as a separate company than when it was a part of General Electric. This also applies to providers of capital—Synchrony might be able to raise capital more effectively as a stand-alone company because investors are better able to evaluate its prospects. A third advantage to carve-outs is that they improve the ability of the parent to offer incentives to a subsidiary's managers. Thus, Synchrony can now offer equity incentives to its managers based on its own stock price rather than that of General Electric.

Equity carve-outs do have some associated costs. First, the underwriting commission involved in a carve-out is larger than for an equity offering by the parent. Second, because an equity carve-out is a type of initial public offering, there is a potential for underpricing the new offering. Third, key managers of the subsidiary must spend a significant amount of time marketing the new stock. Fourth, there are costs associated with the minority interest that is created in the carve-out. For example, the subsidiary's new board of directors must monitor all transactions between the subsidiary and the parent to ensure that the minority investors are not being exploited. Finally, there are additional costs such as annual reports, SEC filings, analyst presentations, and so on, which now must be borne both by parent and subsidiary.

SELF-TEST

Explain what is meant by an equity carve-out.

On average, equity carve-outs have increased shareholder wealth. What are some potential explanations for this phenomenon?

18-5 Other Ways to Raise Funds in the Capital Markets

IPOs are exciting and play a vital role in stimulating the entrepreneurship and innovation that are vital for economic growth. However, the funds raised through IPOs are only a small fraction of the total funding raised from commercial banks and capital markets. In 2014, U.S. companies raised about $1.5 trillion in bonds and $312 billion in equity.[11] Of this $1.812 trillion total debt and equity, about 5% was raised in IPOs. We discuss other ways that firms raise cash from capital markets in the following sections.[12]

18-5a Preliminary Decisions

Before raising capital, a firm must make some initial, preliminary decisions, which include the following:

1. *Dollars to be raised.* How much new capital is needed?
2. *Type of securities used.* Should common stock, preferred stock, bonds, hybrid securities, or a combination be used? Should the capital be public securities (which are registered and may be traded freely in the secondary markets) or should it be a private placement that might have restrictions on its subsequent trading? If common stock is to be issued, should it be done as a preemptive rights offering to current shareholders or by a direct sale to the general public?
3. *Competitive bid versus a negotiated deal.* Should the company simply offer a block of its securities for sale to the highest bidder, or should it negotiate a deal with an investment bank? These two procedures are called **competitive bids** and **negotiated deals**, respectively. Only about 100 of the largest firms listed on the NYSE, whose securities are already well known to the investment banking community, are in a position to use the competitive bidding process. The investment banks must do a great deal of investigative work ("due diligence") to bid on an issue unless they are already quite familiar with the firm, and such costs would be too high to make it worthwhile unless the bank was sure of getting the deal. Therefore, except for the largest firms, offerings of stock and bonds are generally on a negotiated basis. The exceptions are utilities, which are able to issue debt through competitive bids because the offerings are relatively easy for the investment banks to value and sell to clients.
4. *Selection of an investment bank.* Most deals are negotiated, so the firm must select an investment bank. This can be an important decision for a firm that is going public. On the other hand, an older firm that has already "been to market" will have an

[11]See the Securities Industry and Financial Markets Association (SIFMA) Web site's research and statistics for these and other interesting data: **www.sifma.org/research/statistics.aspx**.

[12]For an excellent discussion of the various procedures used to raise capital, see Jay R. Ritter, "Investment Banking and Securities Issuance," in *North-Holland Handbook of the Economics of Finance*, George Constantinides, Milton Harris, and René Stulz, eds. (Amsterdam: North-Holland, 2002). Also see Claudio Loderer, John W. Cooney, and Leonard D. Van Drunen, "The Price Elasticity of Demand for Common Stock," *Journal of Finance*, June 1991, pp. 621–651.

established relationship with an investment bank. However, it is easy to change banks if the firm is dissatisfied. Different investment banking houses are better suited for different companies. For example, Goldman Sachs and Morgan Stanley are the leading tech-IPO underwriters. Investment banking houses sell new issues largely to their own regular brokerage customers, so the nature of these customers has a major effect on the ability of the house to do a good job for corporate issuers. Finally, a major factor in choosing an underwriter is the reputation of the analyst who will cover the stock in the secondary market, because a strong buy recommendation from a well-respected analyst can trigger a sharp price run-up.

18-5b Seasoned Equity Offerings

When a company with publicly traded stock issues additional shares, this is called a **seasoned equity offering**, also known as a *secondary* or *follow-on offering*. Because the stock is already publicly traded, the offering price will be based upon the existing market price of the stock. Typically, the investment bank buys the securities at a prescribed number of points below the closing price on the last day of registration. For example, suppose that in August 2016 the stock of Microwave Telecommunications Inc. (MTI) had a price of $28.60 per share and that the stock had traded between $25 and $30 per share during the previous 3 months. Suppose further that MTI and its underwriter agreed that the investment bank would buy 10 million new shares at $1 per share below the closing price on the last day of registration. If the stock closed at $25 on the day the SEC released the issue, then MTI would receive $24 per share. Typically, such agreements have an escape clause that provides for the contract to be voided if the price of the securities drops below some predetermined figure. In the illustrative case, this "upset" price might be set at $24 per share. Thus, if the closing price of the shares on the last day of registration had been $23.50, MTI would have had the option of withdrawing from the agreement.

The investment bank will have an easier job if the issue is priced relatively low. However, the issuer naturally wants as high a price as possible. A conflict of interest on price therefore arises between the investment bank and the issuer. If the issuer is financially sophisticated and makes comparisons with similar security issues, the investment bank will be forced to price close to the market.

As we discussed in Chapter 15, the announcement of a new stock offering by a mature firm is often taken as a negative signal—if the firm's prospects were good, management would not want to issue new stock and thus share the rosy future with new stockholders. Therefore, the announcement of a new offering is taken as bad news. Consequently, the price will probably fall when the announcement is made, so the offering price will probably have to be set at a price below the pre-announcement market price.

One final point is that *if negative signaling effects drive down the price of the stock, then all shares outstanding, not just the new shares, are affected*. Thus, if MTI's stock should fall from $28.60 to $25 per share as a result of the financing and remains at the new level, then the company's shareholders would incur a loss of $3.60 on each of the 50 million shares previously outstanding, or a total market value loss of $180 million. This loss, like underwriting expenses, is a flotation cost, and it should be considered as a cost associated with the stock issue. Of course, if the company's prospects really were poorer than investors thought, then the price decline would have occurred sooner or later anyway. On the other hand, if the company's prospects are really not all that bad (the signal was incorrect), then over time MTI's price should move back to its previous level. Yet even if the price does revert to its former level, there will have been a transfer of wealth from the original shareholders to the new shareholders.

resource

See **Web Extension 18A** on the textbook's Web site for a discussion of rights offerings.

To prevent dilution due to a regular seasoned equity offering, companies occasionally sell additional shares of stock through a **rights offering** (also called a **preemptive rights offering**). The issuing company gives the owner of each share of outstanding stock a "right," which is similar to a stock option: Each right's holder has the option to purchase a specified number of new shares of the company's stock at a specified purchase price on a certain date. The purchase price usually is very low relative to the current stock price, so the rights are valuable and will be exercised. The rights usually are transferable, so a shareholder can sell the right if she so chooses. This allows each shareholder the opportunity to maintain a proportional ownership stake in the company, but it also gives each shareholder a chance to receive cash from selling the right if the shareholder doesn't want to maintain a proportional ownership. See ***Web Extension 18A*** for more details and numerical examples.

18-5c Shelf Registrations

The selling procedures described so far, including the 20-day waiting period after registration with the SEC, apply to most security sales. However, under the SEC's Rule 415, large, well-known public companies that issue securities frequently may file a master registration statement with the SEC and then update it with a short-form statement just prior to each individual offering. Under this procedure, a company can decide at 10 a.m. to sell securities and have the sale completed before noon. This procedure is known as **shelf registration** because, in effect, the company puts its new securities "on the shelf" and then sells them to investors when it feels the market is "right." Firms with less than $150 million in stock held by outside investors cannot use shelf registrations. The rationale for this distinction is to protect investors who may not be able to obtain adequate financial data about a little-known company in the short time between announcement of a shelf issue and its sale. Shelf registrations have two advantages over standard registrations: (1) lower flotation costs and (2) more control over the timing of the issue.[13]

18-5d Private Placements

The 1933 Securities Act regulates the issuance and subsequent trading of securities. Public offerings must be registered with the SEC, but several exemptions allow companies meeting certain conditions to issue unregistered securities in a process called a private placement.[14] The regulations are complex, but the basic idea is to speed up the process by allowing companies to offer securities to accredited investors, such as financial institutions, security dealers, and high-wealth individuals. The primary advantages of private placements are: (1) lower flotation costs and (2) greater speed, because the securities do not have to go through the SEC registration process at the time they are offered.

[13]In 2005, the SEC began allowing very large firms, known as "well known seasoned issuers" or WKSIs, even greater flexibility in selling shelf-registered shares. WKSIs may now bypass SEC review and automatically shelf-register an unspecified number of securities to sell at times of their choosing. This speeds up even more the process for these large issuers. For more on shelf registrations, see David J. Denis, "The Costs of Equity Issues Since Rule 415: A Closer Look," *Journal of Financial Research*, Spring 1993, pp. 77–88.

[14]Following is a brief and simplified explanation of the major exemptions. Regulation D permits the sale of securities to accredited investors but places restrictions on the subsequent trading of those securities. Rule 144A allows qualified institutional buyers to trade restricted securities among themselves, including securities issued by non-U.S. companies. Regulation S allows U.S. companies to sell unregistered securities abroad. Section 4(2) allows the sale of unregistered securities if the purchaser is knowledgeable and agrees not to resell them to the public.

Private placements are a very important source of financing. In 2010, U.S. companies raised about $1.16 trillion from private placements of debt and equity versus about $1.07 trillion from public offerings.[15]

PRIVATE PLACEMENTS OF EQUITY

Sometimes a privately held firm makes a private placement of equity. For example, Facebook placed $1 billion of common stock with non-U.S. investors in 2011. At other times it is a public company making a private placement. For example, General Growth Properties (GGP), which develops real estate properties such as shopping malls, raised $6.8 billion by selling stock directly to a consortium of investment funds, including Pershing Square Capital Management and Blackstone Group. Because GGP is a publicly held company, this is called a **private placement of public equity (PIPE)**. The most common type of private placement occurs when a company places securities directly with a financial institution, often an insurance company or a pension fund.

Many large companies make equity investments in suppliers or in start-up companies that are developing a related technology. For example, Microsoft's 2014 annual report showed $11.9 billion of investments in the common and preferred stock of other companies.

PRIVATE PLACEMENTS OF DEBT

Before 1990, debt could be issued privately (without SEC registration), but the purchasers faced restrictions on their abilities to resell the debt. This changed in 1990 with SEC Rule 144A, which allows qualified institutional buyers to trade unregistered securities among themselves. This opened the door for non-U.S. companies to raise capital in the states. In addition, subsequent amendments permit Rule 144A securities to be registered shortly after they have been issued, providing companies a quicker way to issue debt that ultimately will trade in public markets. The increased liquidity has made private placement of debt the preferred choice, with the majority of debt being placed privately rather than being issued publicly.

18-5e Securitization

In Chapter 1, we discussed securitization in the context of mortgage markets, and now we discuss it in the context of capital formation. As the term is generally used, a **financial security** refers to a publicly traded financial instrument as opposed to a privately placed instrument. Thus, securities have greater liquidity than otherwise similar instruments that are not traded in an open market. The process of creating a financial security is called **securitization**.

Securitization occurs in two ways. First, a debt instrument that formerly was rarely traded becomes actively traded, usually because the size of the market increases and the terms of the debt instrument become more standardized. For example, this has occurred with commercial paper and junk bonds, both of which are now considered to be securities.

Second, a security can be created by the pledging of specific assets, resulting in the creation of **asset-backed securities**. The oldest type of asset securitization was in the mortgage industry, as we described in Chapter 1. Today, many different types of assets are used as collateral, including auto loans, and credit card balances.

[15]See a special SEC report by Vlad Ivanov and Scott Bauguess, "Capital Raising in the U.S.: The Significance of Unregistered Offerings Using the Regulation D Exemption," February 2012, **www.sec.gov/info/smallbus/acsec/acsec103111_analysis-reg-d-offering.pdf**.

Where There's Smoke, There's Fire

For an unusual example of securitization, consider the 1998 settlement of several lawsuits in which the major tobacco firms agreed to pay a percentage of their cigarette revenues each year to state governments. The payments, which totaled over $7.3 billion in 2012, were intended to compensate states for costs due to smoking-related illness and for expenses related to anti-smoking campaigns. It sounds like a reasonable settlement, but many states have used the money for other purposes.

For example, in 2001 Virginia's governor proposed using the funds to pay for a tax cut, and for many years thereafter Virginia allocated 40% of its annual share of the settlement to its general fund, 50% to a fund for economic assistance to tobacco farmers, and 10% to smoking cessation programs. Prior to 2008, Tennessee committed no funds at all to smoking prevention. In 2012, Tennessee received $139 million from the settlement and devoted only $200,000 to prevention programs. The rest went to fund general government operations.

Some states didn't want to wait on the annual payments, so they securitized the future stream of settlement cash flows by issuing tobacco bonds—investors gave the state cash on the issue date, and the states will pay the investors annually with future tobacco settlement revenues. In 2012, California, Iowa, Louisiana, Minnesota, New Jersey, New York, Rhode Island, South Carolina, Virginia, Washington, and West Virginia all had tobacco bonds outstanding.

As with the annual payments, not all bond proceeds were used for the intended purpose. For example, Wisconsin sold over $1 billion of tobacco bonds in 2002, much of which was used to balance the budget that year. In March 2012, Alabama issued $92.8 million of tobacco bonds, using the proceeds to retire tobacco bonds they had issued 12 years earlier, which were used to make grants to companies for economic development and to pay for flood levee improvements.

Virginia issued $448 million worth of tobacco bonds in 2005. Instead of spending it in the annual budget as Wisconsin did, Virginia contributed $390 million to the Tobacco Indemnification and Community Revitalization Endowment, a program whose earnings subsidize tobacco farmers based on the amount of tobacco they produced in 1998.

Some observers might say that the tobacco settlement is going up in smoke.

Sources: See Mike Cherney, "New Flavor of Tobacco Bonds," *The Wall Street Journal*, March 17, 2012, B6; also see **www.tobaccofreekids.org/facts_issues/fact_sheets/policies/settlements_us_state/payments/** and **http://kff.org/other/state-indicator/tobacco-settlement-payments/#**.

The asset securitization process involves the pooling and repackaging of loans secured by relatively homogeneous, small-dollar assets (such as an automobile) into liquid securities. Usually several different financial institutions are involved, with each playing a different functional role. For example, an auto dealer might sell a car, the auto manufacturer's lending operation might originate the loan, an investment bank might pool similar car loans and structure the security, a federal agency might insure against credit risk, a second investment bank might sell the securities, and a pension fund might supply the final capital.

A similar process can occur with equipment or cell-tower leases, student loans, or more exotic assets like Miramax's 2011 sale of $550 million of bonds backed by revenues from its library of films, including *Pulp Fiction* and *Good Will Hunting*.[16]

The process of securitization lowers costs and increases the availability of funds to borrowers, with the risk being transferred to the investor. But as we described in Chapter 1, if loans are originated to borrowers with poor credit risk, then the cash flows received by the ultimate investor are likely to be low.

18-6 Investment Banking Activities

Investment banks underwrite IPOs, underwrite seasoned equity offerings, and manage debt offerings. In other words, investment banks help firms raise capital, and lots of it: Table 18-2 shows that investment banks helped firms raise over *$6 trillion* during 2013. Investment banks also engage in other activities. Because of increasingly relaxed regulations that culminated with the repeal of the Glass-Steagall Act in 1999, there is no longer a clear delineation between investment banks, brokerage firms, and commercial banks. In the following sections, we discuss activities that are primarily associated with the investment banking arm of the financial conglomerates.

18-6a Mergers and Acquisitions

Many investment banks are actively involved in mergers and acquisitions (M&As) through three activities.

1. *Matchmaking.* Investment banks often find potential targets for acquirers, sometimes earning a finder's fee if the deal is successful.
2. *Advising.* Both the target and acquirer must document that the deal is "fair" for their stockholders by performing a due diligence valuation analysis. Investment banks often provide consulting advice during this stage of the M&A.
3. *Underwriting.* Most M&As require that new capital be raised. Investment banks underwrite these new issues.

Underwriting is the most lucrative of these activities, but if the deal falls through, then no new securities will be underwritten. This makes one wonder how unbiased investment bankers are when finding targets and providing advice during negotiations.

TABLE 18-2
Top Five Underwriters of Global Debt and Equity in 2014

Manager	Proceeds (Billions)
JP Morgan	$ 493
Citi	419
Deutsche Bank AG	415
Barclays	383
Bank of America Merrill Lynch	382
Industry total	$6,629

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

18-6b Securitization

Investment banks often provide advice to financial institutions regarding the securitization of the institutions' loans or leases. In fact, investment banks frequently provide turnkey service by purchasing an institution's loans, securitizing the loans, and selling the newly created securities. Thus, the investment bank becomes the securitizer, not just the advisor. During the build-up to the global economic crisis, many investment banks were unable to sell all the mortgage-backed securities they created and were left holding some of them in their own portfolios. When the original borrowers began defaulting, the values of these securities owned by the investment banks plummeted, contributing to the downfall of Bear Stearns, Lehman Brothers, and Merrill Lynch.

18-6c Asset Management

Many investment banking companies create investment funds, such as a limited partnership (LP) that might invest in real estate in developing nations or an LP that might seek to exploit mispricing in various asset classes. In other words, they run their own hedge funds, which can be quite lucrative. Like any other hedge fund, they raise capital for these funds from a variety of sources. But unlike other hedge funds, investment banks often have access to a special source—their own clients!

Here is how that works. Many investment banks have "wealth management" divisions or subsidiaries that provide investment advice to wealthy individuals or institutions such as pension funds. As advisors, they recommend investment strategies, including specific investments, to their clients. Some of these investments might be individual securities or mutual funds managed by other organizations. However, some of the recommended investments might be funds managed by the advisor's own investment bank. These might be great investments, but there is at least the appearance of a conflict of interest when advisors recommend funds managed by their own company.

In addition to managing clients' money, investment banks also invest their own money (actually, the money of their own stockholders and creditors) in financial securities. Sometimes the choice of investment is intentional, but sometimes it is not—as we mentioned previously, some investment banks were unable to sell all the mortgage-backed securities they created and were left holding some in their own portfolios.

18-6d Trading Operations

Many investment banking companies have trading operations through which they actively trade on the behalf of clients. For example, a client might need help in selling a large block of debt. Also, investment banking companies usually make a market in the stock of companies that they took public. Thus, these activities can be viewed as services provided to clients.

However, many investment banks also view their trading operations as profit centers. In other words, the traders try to buy low and sell high, and in the process they sometimes accumulate large positions that become difficult to unload.

What Was the Role of Investment Banks?

There is plenty of blame to spread around for the cause of the global economic crisis, but investment banks certainly played a special role.

Among their many strategic errors, investment banks morphed from organizations that earned money primarily through fee-generating activities into organizations that earned money as highly leveraged investors. Investing is an inherently risky business, especially when the investments include extremely complicated mortgage-backed securities and credit default swaps. Investing becomes even riskier when you borrow $33 for every $1 of equity, as many investment banks did. This strategy is great if you earn more than you owe on your debt because leverage magnifies returns, and these magnified returns generated gigantic bonuses for senior managers at the investment banks. But it doesn't take too much of a decline in asset values and investment income to cause failure. In essence, the investment bankers were willing to risk it all for the chance of mind-boggling bonuses.

In addition to selling toxic investments (such as complex mortgage-backed securities) to pension funds and other financial institutions, the interconnectedness of failing investment banks threatened the entire world economy. Lehman Brothers had been borrowing short term in the commercial paper market and investing long term in risky assets. When those assets failed, Lehman defaulted on its commercial paper obligations, many of which were owned by money market funds. This caused some funds, like the large Primary Reserve Fund, to "break the buck," which means that their reported net asset value dropped below $1, something that investors never expected. This led to a run on many money market funds and a huge disruption in the financial commercial paper markets.

Investment banks also were major players in the market for credit default swaps (CDS). If investment banks defaulted on their CDS, then it would cause potentially bankrupting financial distress at many other financial institutions.

Because many investment banks are subsidiaries of bank holding companies, the failure of the investment banks threatened the viability of the holding company and its other subsidiaries, such as commercial banks, which began limiting the credit they provided to their borrowers. In short, the financial crisis spread to the nonfinancial sector as financial institutions began cutting back on the credit they provided to the nonfinancial sector.

The investment banking landscape has certainly changed during the global economic crisis. Bear Stearns was acquired by JP Morgan, Lehman Brothers went bankrupt and was sold piecemeal, Merrill Lynch was acquired by Bank of America, and several investment banks, including Goldman Sachs, rechartered themselves as banks to qualify for TARP funds.

18-7 The Decision to Go Private

In a **going private** transaction, the entire equity of a publicly held firm is purchased by a small group of investors, with the firm's current senior management usually maintaining or increasing their ownership stakes. The outside investors typically place directors on the now-private firm's board and arrange for the financing needed to purchase the publicly held stock. When the financing involves substantial borrowing, as it usually does, it is known as a **leveraged buyout (LBO)**. In some cases, the current management group raises the financing and acquires all of the equity of the company; these are called management buyouts (MBOs).

The outside equity in a buyout often comes from a **private equity (PE) fund**, which is a limited liability partnership created to own and manage investments in nontraded equity. Private equity funds raise money from wealthy investors and institutions such as university endowments, pension funds, and insurance companies. The PE funds then take public firms private or invest in firms that

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

already are privately held. Most PE funds plan on improving the companies' performance and then harvesting their investments by selling the company, perhaps in an IPO.[17]

Regardless of the deal's structure, going private initially affects the right-hand side of the balance sheet, the liabilities and capital, and not the assets: Going private simply rearranges the ownership structure. Thus, going private involves no obvious operating economies, yet the new owners are generally willing to pay a large premium over the stock's current price in order to take the firm private.

For example, in 2006 HCA Inc., a large health care corporation, was taken private by the original family owners, the Frists, and a group of private equity firms and investment banks, including Bain Capital and Kohlberg Kravis Roberts & Co. (KKR), for $51 per share. The stock had been selling in the low $40s the month prior to the announcement. The investors put up about $4.9 billion in equity and borrowed about $28 billion to fund the purchase of equity and refinance some of the company's debt. It is hard to believe that these sophisticated investors and managers would knowingly pay too much for the firm. Thus, the investors and managers must have regarded the firm as being grossly undervalued, even at $51 per share, or else thought that they could significantly boost the firm's value under private ownership. In fact, after 4 years as a private company HCA went public again in 2011. The owners received $4.3 billion in dividends during 2010 and an additional $1.1 billion in cash from shares they sold in the IPO, almost completely recovering their initial investment. After the IPO the stock was worth about $16 billion, with about 25% of the company in public hands, and 75%, or about $12 billion, remaining with the private equity fund. Although the total return the investors ultimately earn depends on how much they receive for the shares they still hold in the company, the $4.9 billion investment has currently reaped cash and stock worth some $16 billion. Not a bad return for a 4-year investment!

This suggests that going private can increase the value of some firms sufficiently to enrich both managers and public stockholders. Other large companies going private recently include Dell (2013), Frederick's of Hollywood (2013), the piano maker Steinway Musical Instruments (2013), and H.J. Heinz Co. (2013).

The primary advantages to going private are: (1) administrative cost savings, (2) increased managerial incentives, (3) increased managerial flexibility, (4) increased shareholder oversight and participation, and (5) increased use of financial leverage, which of course reduces taxes. We discuss each of these advantages in more detail in the following paragraphs.

1. *Administrative cost savings.* Because going private takes the stock of a firm out of public hands, it saves on the time and costs associated with securities registration, annual reports, SEC and exchange reporting, responding to stockholder inquiries, and so on.
2. *Increased managerial incentives.* Managers' increased ownership and equity incentive plans mean that managers benefit more directly from their own efforts; hence, managerial efficiency tends to increase after going private. If the firm is highly successful, then its managers can easily see their personal net worth increase twentyfold, but if the firm fails, then its managers end up with nothing.
3. *Increased managerial flexibility.* Managers at private companies do not have to worry about what a drop in the next quarter's earnings will do to the firm's stock price, so they can focus on long-term, strategic actions that ultimately will have the greatest

positive impact on the firm's value. Managerial flexibility concerning asset sales is also greater in a private firm, because such sales need not be justified to a large number of shareholders with potentially diverse interests.

4. *Increased shareholder oversight and participation.* Going private typically results in replacing a dispersed, largely passive group of public shareholders with a small group of investors who take a much more active role in managing the firm. These new equity investors have a substantial position in the private firm; hence, they have a greater motivation to monitor management and to provide incentives to management than do the typical stockholders of a public corporation. Further, the new nonmanagement equity investors—frequently private equity firms, such as KKR, Carlyle Group, or Blackstone Group—are typically represented on the board, and they bring sophisticated industry and financial expertise and hard-nosed attitudes to the new firm.
5. *Increased financial leverage.* Going private usually entails a drastic increase in the firm's use of debt financing, which has two effects. First, the firm's taxes are reduced because of the increase in deductible interest payments, so more of the operating income flows through to investors. Second, the increased debt service requirements force managers to hold costs down to ensure that the firm has sufficient cash flow to meet its obligations—a highly leveraged firm simply cannot afford any fat.

One might ask why all firms are not privately held. The answer is that, although there are real benefits to private ownership, there are also benefits to being publicly owned. Most notably, public corporations have access to large amounts of equity capital on favorable terms, and for most companies, the advantage of access to public capital markets dominates the advantages of going private. Also, note that most companies that go private end up going public again after several years of operation as private firms. In addition to HCA, for example, Celanese AG, a global chemical company, went public in 1999. It was taken private in 2004 by Blackstone Capital Partners, a PE firm, and then taken public again in 2005.

18-8 Refunding Operations

A great deal of corporate debt was sold during the late 1990s. Because the call protection on much of this debt has ended and because interest rates have fallen since the debt was issued, bond **refunding operations** make sense for many companies. In a typical refunding operation, an investment bank assists a company in calling old debt and issuing new debt at a lower interest rate.

Even though the new interest rate is lower, there are initial costs and tax implications that must be considered before undertaking a refunding operation. The basic approach is to estimate the incremental after-tax cash flows associated with the refunding. The cash flows in a refunding decision are due to the presence of debt, so the cash flows should be discounted at the after-tax cost of debt. The best way to examine the refunding decision is through an example, shown in Figure 18-1 and explained as follows.

18-8a Analysis of Microchip's Refunding Operation

Microchip Computer Company has a $60 million bond issue outstanding that has a 12% annual coupon interest rate and 20 years remaining to maturity. This issue, which was sold 5 years ago, had flotation costs of $3 million that the firm has been amortizing on a straight-line basis over the 25-year original life of the issue. The bond has a call provision that makes it possible for the company to retire the issue at this time by calling the bonds in at a 10% call premium. Investment banks have assured the company that it could sell an additional $60 million to $70 million worth of new 20-year bonds at an interest rate of 9%.

To ensure that the funds required to pay off the old debt will be available, the new bonds will be sold 1 month before the old issue is called; thus, for 1 month the company will have to pay interest on two issues. Current short-term interest rates are 6%. Predictions are that long-term interest rates are unlikely to fall below 9%.[18] Flotation costs on a new refunding issue will amount to $2,650,000, and the firm's marginal federal-plus-state tax rate is 40%. Should the company refund the $60 million of 12% bonds? The following analysis helps answer this question.

18-8b Steps in a Refunding Analysis

The following steps outline the decision process; they are summarized in the spreadsheet in Figure 18-1. Panel A presents the input data and Panel B determines the after-tax initial investment.

STEP 1: DETERMINE THE INVESTMENT OUTLAY REQUIRED TO REFUND THE ISSUE

Although Microchip must spend $6 million on the call premium, this is a deductible expense in the year the call is made. Because the company is in the 40% tax bracket, it saves $2.4 million in taxes; therefore, the after-tax cost of the call is only $3.6 million, as shown here and in Panel B, Line 1:

$$\text{Before tax: } 0.10(\$60{,}000{,}000) = \$6{,}000{,}000$$

$$\begin{aligned}\text{After tax: } \$6{,}000{,}000(1 - T) &= \$6{,}000{,}000(0.6)\\ &= \$3{,}600{,}000\end{aligned}$$

Flotation costs on the new issue will be $2,650,000, as shown in Line 2. This amount cannot be expensed for tax purposes, so it provides no immediate tax benefit. Even though the new bonds will be issued one month prior to calling the old bonds, this analysis assumes that the cash flows occur simultaneously. A more detailed analysis could be done on a monthly basis, but the results will be almost identical to the ones shown here. Sometimes the benefits of additional realism are not worth the costs of additional complexity, and that is the situation here.

The old issue has a remaining unamortized flotation cost of (20/25) ($3,000,000) = $2,400,000. If the issue is retired, then the unamortized flotation cost may be recognized immediately as an expense, thus creating an after-tax savings of $2,400,000(T) = $960,000, as shown on Line 3. Because this is a cash inflow, it is shown as a positive number.

Recall that the new bonds will be issued one month prior to calling the old bonds. Therefore, one month's "extra" interest on the old issue, after taxes, is $360,000, as shown in Line 4:

$$\begin{aligned}\text{Interest cost} &= (\text{Dollar amount})(1/12 \text{ of } 12\%)(1 - T)\\ &= (\$60{,}000{,}000)(0.01)(0.6) = \$360{,}000\end{aligned}$$

However, the proceeds from the new issue can be invested in short-term securities for 1 month. Thus, $60 million invested at a rate of 6% will return $180,000 in after-tax interest, as shown in Line 5:

$$\begin{aligned}\text{Interest earned} &= (\$60{,}000{,}000)(1/12 \text{ of } 6\%)(1 - T)\\ &= (60{,}000{,}000)(0.005)(0.6) = \$180{,}000\end{aligned}$$

[18]The firm's management has estimated that interest rates will probably remain at their present level of 9% or else rise; there is only a 25% probability that they will fall further.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Line 6 shows the total after-tax investment outlay required to refund the bond issue, summarized below:[19]

Call premium	($3,600,000)
Flotation costs, new	(2,650,000)
Flotation costs, old, tax savings	960,000
Net additional interest	(180,000)
Total investment	($5,470,000)

STEP 2: CALCULATE THE PRESENT VALUE OF THE ANNUAL AFTER-TAX FLOTATION COST EFFECTS

For tax purposes, flotation costs must be amortized over the life of the new bond, which is 20 years. Therefore, the annual tax deduction in Line 7 is:

$$\frac{\$2{,}650{,}000}{20} = \$132{,}500$$

Because the firm is in the 40% tax bracket, it has a tax savings of $\$132{,}500(0.4) = \$53{,}000$ a year for 20 years. This is an annuity of $53,000 for 20 years. The firm, however, will no longer receive a tax deduction of $120,000 a year due to the old bond's flotation costs, so it loses an after-tax benefit of $48,000 a year, as shown in Line 8. Therefore, the net after-tax difference between the amortization tax effects of flotation on the new and old issues is $5,000 a year ($\$53{,}000 - \$48{,}000 = \$5{,}000$), shown in Line 9.

The present value of the annual net after-tax flotation cost benefit is the present value of the 20 years of $5,000 in savings. As stated previously, the appropriate interest rate is the after-tax cost of the new debt, which is $5.4\% = 9\%(1 - 0.40)$. The present value of this annuity can be found using a financial calculator, with N = 20, I/YR = 5.4, PMT = 5000, and FV = 0. Solving for PV shows that the flotation cost savings have a present value equal to $60,251. Line 12 in Figure 18-1 shows this same result using *Excel*.

STEP 3: CALCULATE THE PRESENT VALUE OF THE ANNUAL AFTER-TAX INTEREST SAVINGS

The annual after-tax interest on the old issue is $4.32 million, shown in Line 13 of Figure 18-1:

$$(\$60{,}000{,}000)(0.12)(0.6) = \$4{,}320{,}000$$

The new issue has an annual after-tax cost of $3,240,000, shown in Line 14:

$$(\$60{,}000{,}000)(0.09)(0.6) = \$3{,}240{,}000$$

[19]The investment outlay (in this case, $5,470,000) is usually obtained by increasing the amount of the new bond issue. In the example given, the new issue would be $65,470,000. However, the interest on the additional debt *should not* be deducted later at Step 3 because the $5,470,000 itself will be deducted later at Step 4. If additional interest on the $5,470,000 were deducted at Step 3, then interest would, in effect, be deducted twice. The situation here is exactly like that in regular capital budgeting decisions. Even though some debt may be used to finance a project, interest on that debt is not subtracted when developing the annual cash flows. Instead, the annual cash flows are *discounted* at the project's cost of capital.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Thus, the net annual interest savings is $1,080,000, shown in Line 15 and summarize here:

Interest on old bonds, after tax	$4,320,000
Interest on new bonds, after tax	(3,240,000)
Annual interest savings, after tax	$1,080,000

The present value of the annual net after-tax interest savings is the present value of the 20 years of $1,080,000 in savings. The PV of the $1,080,000 annual after-tax interest savings is found with N = 20, I/YR = 5.4, PMT = 1080000, and FV = 0; solving for PV shows that the present value of after-tax interest cost savings is $13,014,174.

STEP 4: DETERMINE THE TOTAL NPV OF THE REFUNDING OPERATION

The previous steps determined the initial outlay, present value of flotation effects, and present value of interest savings. Line 22 of Figure 18-1 shows the total NPV of $7,604,425, summarized here:

Net investment outlay	−$5,470,000
PV of after-tax flotation effects	$ 60,251
PV of after-tax interest savings	13,014,174
NPV from refunding	$7,604,425

Because the NPV of refunding is positive, Microchip should proceed with additional analysis, as described next.

TVA Ratchets Down Its Interest Expenses

In 1998, TVA raised $575 million in 30-year debt. If it had issued fixed-rate debt, it would be stuck with high coupon payments if interest rates in the market fall. If it had issued floating-rate debt, it would be stuck with high coupon payments if interest rates rise. If it had issued callable debt, then it could refinance if interest rates fall. But the costs of refunding are high, and TVA would have to agonize over the decision of whether to refund or wait in the hopes that rates will fall. None of these three choices seemed desirable, so TVA issued a new type of security that finesses these problems.

The new bonds are officially called Putable Automatic Rate Reset Securities (PARRS), but they are commonly known as ratchet bonds. These bonds have a feature that resets the coupon rate each year, starting in 2003, to 94 basis points over the rate on the prevailing 30-year Treasury bond—provided the new coupon would be lower than the ratchet bond's current coupon. In other words, the coupon on the bond will fall if interest rates fall, but it will never increase from year to year, allowing TVA to lock in the lowest interest rates that prevail during the bond's life. In essence, TVA gets to refund its debt in any year when rates fall; hence, the term "ratchet."

The 94-basis-point spread is higher than the spread over Treasuries that normally exists on TVA's noncallable bonds, given its bond rating. However, if the bond rating deteriorates, then investors can "put" the bond by selling it back to TVA. The net effect is that investors are exposed to interest rate risk but not to credit risk, and they are compensated for interest rate risk by the relatively high spread.

These bonds were originally issued with a 6.750% coupon, and on the first reset date (June 1, 2003) the rate ratcheted down to 5.952%, reflecting the decline in long-term interest rates since 1998. By November 2013, long-term interest rates had fallen so that the coupon rate on the PARRS was ratcheted down to 3.830%.

18-8c Refund Now or Later?

Although the analysis shows that the refunding would increase the firm's value, would refunding *at this time* truly maximize the firm's expected value? If interest rates continue to fall, then the company might be better off waiting, for this would increase the NPV of the refunding operation even more. The mechanics of calculating the NPV in a refunding are easy, but the decision of *when* to refund is not at all simple because it requires a forecast of future interest rates. Thus, the final decision on refunding now versus waiting for a possibly more favorable time is a judgment call.

To illustrate the timing decision, assume Microchip's managers forecast that long-term interest rates have a 50% probability of remaining at their present level of 9% over the next year. However, there is a 25% probability that rates could fall to 7% and a 25% probability they could rise to 11%. Further, assume that short-term rates are expected to remain 3 percentage points below long-term rates and that the call premium would be reduced by 5% if the call were delayed for 1 year.

The refunding analysis could then be repeated, as previously, but as if it were a year later. Thus, the old bonds would have only 19 years remaining to maturity. We performed the analysis and found the NPV distribution of refunding 1 year from now:

Probability	Long-Term Interest Rate	NPV of Refunding 1 Year from Now
25%	7%	$17,947,071
50	9	7,390,083
25	11	(1,359,939)

At first blush, it would seem reasonable to calculate the expected NPV of refunding next year in terms of the probability distribution. However, that would not be correct. If interest rates did rise to 11%, Microchip would not refund the issue; therefore, the actual NPV if rates rose to 11% would be zero. The expected NPV from waiting 1 year is $0.25(\$17{,}947{,}071) + 0.50(\$7{,}390{,}083) + 0.25(\$0) = \$8{,}181{,}809$, versus $7,604,425 if refunding occurred today.

Even though the expected NPV of refunding in 1 year is higher, Microchip's managers would probably decide to refund today. The $7,604,425 represents a sure increase in firm value, whereas the $8,181,809 is risky. Also, proper comparison requires that the $8,181,809 be discounted back 1 year to today. Microchip's managers should opt to delay refunding only if the expected NPV from later refunding is sufficiently above today's sure NPV to compensate for the risk and time value involved.

Clearly, the decision to refund now versus refund later is complicated by the fact that there would be numerous opportunities to refund in the future rather than just a single opportunity 1 year from now. Furthermore, the decision must be based on a large set of interest rate forecasts, a daunting task in itself. Fortunately, financial managers making bond refunding decisions can now use the values of derivative securities to estimate the value of the bond issue's embedded call option. If the call option is worth more than the NPV of refunding today, the issue should not be immediately refunded. Rather, the issuer should either delay the refunding to take advantage of the information

obtained from the derivative market or actually create a derivative transaction to lock in the value of the call option.[20]

SELF-TEST

How is bond refunding like a capital budgeting project?

18-9 Managing the Risk Structure of Debt with Project Financing

Historically, many large projects such as the Alaska pipeline have been financed by what is called **project financing**, and investment banks often help put these deals together.[21] Project financing has been used to finance energy explorations, oil tankers, refineries, and electric generating plants. Generally, one or more firms will sponsor the project, putting up the required equity capital, while the remainder of the financing is furnished by lenders or lessors. Most often, a separate legal entity is formed to operate the project. Normally, the project's creditors do not have full recourse against the sponsors. In other words, the lenders and lessors must be paid from the project's cash flows and from the sponsors' equity in the project, because the creditors have no claims against the sponsors' other assets or cash flows. Often the sponsors write "comfort" letters, giving general assurances that they will strive diligently to make the project successful. However, these letters are not legally binding, so in project financing the lenders and lessors must focus their analysis on the inherent merits of the project and on the equity cushion provided by the sponsors.[22]

Project financing is not a new development. Indeed, back in 1299 the English Crown negotiated a loan with Florentine merchant banks that was to be repaid with 1 year's output from the Devon silver mines. Essentially, the Italians were allowed to operate the mines for 1 year, paying all the operating costs and mining as much ore as they could. The Crown made no guarantees as to how much ore could be mined or the value of the refined silver. A more current example involved GE Capital, the credit arm of General Electric, which recently financed a $72 million project to build an aluminum can plant. The plant is owned by several beverage makers but it is operated independently, and GE Capital must depend on the cash flows from the plant to repay the loan. About half of all project financings in recent years have been for electric generating plants, including plants owned by electric utilities and cogeneration plants operated by industrial companies. Project financings are generally

[20]For a discussion of the time to call and refund, see Andrew J. Kalotay, Deane Yang, and Frank J. Fabozzi, "Refunding Efficiency: A Generalized Approach," *Applied Financial Economics Letters*, 2007, No. 3, pp. 141–146. For more information on the use of derivatives to help make call decisions, see Andrew J. Kalotay and George O. Williams, "How to Succeed in Derivatives without Really Buying," *Journal of Applied Corporate Finance*, Fall 1993, pp. 100–103. For more on bond refunding, see Raymond C. Chiang and M. P. Narayanan, "Bond Refunding in Efficient Markets: A Dynamic Analysis with Tax Effects," *Journal of Financial Research*, Winter 1991, pp. 287–302; David C. Mauer, "Optimal Bond Call Policies under Transactions Costs," *Journal of Financial Research*, Spring 1993, pp. 23–37; and Janet S. Thatcher and John G. Thatcher, "An Empirical Test of the Timing of Bond-Refunding Decisions," *Journal of Financial Research*, Fall 1992, pp. 219–230.

[21]For an excellent discussion of project financing, see Benjamin C. Esty, "Petrozuata: A Case Study on the Effective Use of Project Finance," *Journal of Applied Corporate Finance*, Fall 1999, pp. 26–42.

[22]In another type of project financing, each sponsor guarantees its share of the project's debt obligations. Here the creditors also consider the creditworthiness of the sponsors in addition to the project's own prospects. It should be noted that project financing with multiple sponsors in the electric utility industry has led to problems when one or more of the sponsors has landed in financial trouble. For example, Long Island Lighting, one of the sponsors in the Nine Mile Point nuclear project, became unable to meet its commitments to the project, which forced other sponsors to shoulder an additional burden or else see the project canceled and lose all their investment up to that point. The risk of such default makes many companies reluctant to enter into such projects.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

characterized by large size and a high degree of complexity. However, because project financing is tied to a specific project, it can be tailored to meet the specific needs of both the creditors and the sponsors. In particular, the financing can be structured so that both the funds provided during the construction phase and the subsequent repayments match the timing of the project's projected cash outflows and inflows.

Project financing offers several potential benefits over conventional debt financing. For one, project financing usually restricts the use of the project's cash flows, which means that the lenders—rather than the managers—can decide whether excess cash flows should be reinvested or instead used to reduce the loan balance by more than the minimum required. Conferring this power on the lenders reduces their risks. Project financings also have advantages for borrowers. First, because risks to the lenders are reduced, the interest rate built into a project financing deal may be relatively low. Second, because suppliers of project financing capital have no recourse against the sponsoring firms' other assets and cash flows, project financings insulate the firms' other assets from risks associated with the project being financed. Managers may be more willing to take on a large, risky project if they know that the company's existence would not be threatened if it fails.

Project financings increase the number and type of investment opportunities; hence, they make capital markets "more complete." At the same time, project financings reduce the costs to investors of obtaining information and monitoring the borrower's operations. To illustrate, consider an oil and gas exploration project that is funded using project financing. If the project were financed as an integral part of the firm's normal operations, investors in all the firm's outstanding securities would need information on the project. By isolating the project, the need for information is confined to the investors in the project financing, who need to monitor only the project's operations and not those of the entire firm.

Project financings also permit firms whose earnings are below the minimum requirements specified in their existing bond indentures to obtain additional debt financing. In such situations, lenders look only at the merits of the new project, and its cash flows may support additional debt even though the firm's overall situation does not. Project financings also permit managers to reveal proprietary information to a smaller group of investors, so project financings increase the ability of a firm to maintain confidentiality. Finally, project financings can improve incentives for key managers by enabling them to take direct ownership stakes in the operations under their control. By establishing separate projects, companies can provide incentives that are much more directly based on individual performance than is typically possible within a large corporation.

SELF-TEST

What is project financing? What are its advantages and disadvantages?

SUMMARY

- The **Securities and Exchange Commission (SEC)** regulates securities markets.
- **Private placements** are securities offerings to a limited number of investors and are exempt from registration with the SEC.
- **Accredited investors** include the officers and directors of a company, high-wealth individuals, and institutional investors. These investors are eligible to buy securities in private placements.
- An **angel investor** is a wealthy individual who makes an equity investment in a start-up company.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- The managers of a **venture capital fund** are called **venture capitalists (VCs)**. They raise money from investors and make equity investments in start-up companies, called **portfolio companies**.
- **Going public** in an **initial public offering (IPO)** facilitates stockholder diversification, increases liquidity of the firm's stock, makes it easier for the firm to raise capital, establishes a value for the firm, and makes it easier for a firm to sell its products. However, reporting costs are high, operating data must be disclosed, management self-dealings are harder to arrange, the price may sink to a low level if the stock is not traded actively, and public ownership may make it harder for management to maintain control.
- **Investment banks** assist in issuing securities by helping the firm determine the size of the issue and the type of securities to be used, by establishing the selling price, by selling the issue, and, in some cases, by maintaining an after-market for the stock.
- An investment bank may sell a security issue on a **best efforts basis**, or it may guarantee the sale by **underwriting** the issue.
- Before an IPO, the investment bank and management team go on a **roadshow** and make presentations to potential institutional investors.
- An IPO is **oversubscribed** if investors are willing to purchase more shares than are being offered at the IPO price.
- The **spread** is the difference between the price at which an underwriter sells a security and the proceeds that the underwriter gives to the issuing company. In recent years the spread for almost all IPOs has been 7%.
- An **equity carve-out** (also called a **partial public offering** or **spin-out**) is a special IPO in which a publicly traded company converts a subsidiary into a separately traded public company by selling shares of stock in the subsidiary. The parent typically retains a controlling interest.
- SEC Rule 415, also known as **shelf registration**, allows a company to register an issue and then sell that issue in pieces over time rather than all at once.
- A **seasoned equity offering** occurs when a public company issues additional shares of stock.
- A **rights offering** occurs when a public company gives its stockholders the option to purchase a specified number of the new shares. See ***Web Extension 18A*** for more details.
- A **private equity fund** is a limited liability partnership created to own and manage investments in the nontraded equity of firms.
- A company **goes private** when a small group of investors, including the firm's senior management, purchases all of the equity in the company. Such deals usually involve high levels of debt and are commonly called **leveraged buyouts (LBOs)**.
- If a bond has a call provision, then the issuer may **refund (call)** the bond prior to maturity and pay for it with a new debt issue at a lower interest rate.
- In **project financing**, the payments on debt are secured by the cash flows of a particular project.
- An **asset-backed security** represents a claim on a specific portfolio of financial assets, such as a portfolio of credit card debts or mortgages.

QUESTIONS

(18-1) Define each of the following terms:

a. Going public; new issue market; initial public offering (IPO)
b. Public offering; private placement
c. Venture capitalists; roadshow; spread
d. Securities and Exchange Commission (SEC); registration statement; shelf registration; margin requirement; insiders
e. Prospectus; "red herring" prospectus
f. National Association of Securities Dealers (NASD)
g. Best efforts arrangement; underwritten arrangement
h. Refunding; project financing; securitization

(18-2) Many companies that go public with an IPO don't actually need additional cash to continue growing their operations. Why might such a firm decide to go public?

(18-3) The SEC attempts to protect investors who are purchasing newly issued securities by making sure that the information put out by a company and its investment banks is correct and is not misleading. However, the SEC does not provide an opinion about the real value of the securities; hence, an investor might pay too much for some new stock and consequently lose heavily. Do you think the SEC should, as a part of every new stock or bond offering, render an opinion to investors on the proper value of the securities being offered? Explain.

(18-4) How do you think each of the following items would affect a company's ability to attract new capital and the flotation costs involved in doing so?

a. A decision of a privately held company to go public
b. The increasing institutionalization of the "buy side" of the stock and bond markets
c. The trend toward financial conglomerates as opposed to stand-alone investment banking houses
d. Elimination of the preemptive right
e. The introduction in 1981 of shelf registration of securities

(18-5) Before entering a formal agreement, investment banks carefully investigate the companies whose securities they underwrite; this is especially true of the issues of firms going public for the first time. Because the banks do not themselves plan to hold the securities but intend to sell them to others as soon as possible, why are they so concerned about making careful investigations?

SELF-TEST PROBLEMS

Solutions Shown in Appendix A

(ST-1) IPO Number of Shares and Offer Price

Kelley Corporation is considering an IPO. Kelley and its underwriter agree that the company is worth $500 million. Kelley's founders and early investors own 20 million shares of stock. Kelley has no debt, preferred stock, or short-term investments. The underwriters will charge a 7% spread. Kelly wishes to sell enough new shares so that the new investor will own 20% of the company after the IPO. Assume that the direct costs of the IPO are negligible.

a. How many shares should Kelley sell?
b. What is the intrinsic value of Kelley's stock price per share before the IPO?
c. What offer price is fair to Kelley's current owners and to the new shareholders?

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(ST-2) IPO Shares and Money Left on Table

Blue Coral Breweries (BCB) is planning an IPO. Its underwriters have said the stock will sell at $20 per share. The direct costs (legal fees, printing, etc.) will be $800,000. The underwriters will charge a 7% spread.

a. How many shares must BCB sell to net $30 million?
b. If the stock price closes the first day at $22, how much cash has BCB left on the table?
c. What are BCB's total costs (direct, indirect, and underwriting) for the IPO?

PROBLEMS

Answers Are in Appendix B

EASY PROBLEMS 1–2

(18-1) Profit or Loss on New Stock Issue

Security Brokers Inc. specializes in underwriting new issues by small firms. On a recent offering of Beedles Inc., the terms were as follows:

Price to public:	$5 per share
Number of shares:	3 million
Proceeds to Beedles:	$14,000,000

The out-of-pocket expenses incurred by Security Brokers in the design and distribution of the issue were $300,000. What profit or loss would Security Brokers incur if the issue were sold to the public at the following average price?

a. $5 per share
b. $6 per share
c. $4 per share

(18-2) Underwriting and Flotation Expenses

The Beranek Company, whose stock price is now $25, needs to raise $20 million in common stock. Underwriters have informed the firm's management that they must price the new issue to the public at $22 per share because of signaling effects. The underwriters' compensation will be 5% of the issue price, so Beranek will net $20.90 per share. The firm will also incur expenses in the amount of $150,000. How many shares must the firm sell to net $20 million after underwriting and flotation expenses?

INTERMEDIATE PROBLEMS 3–5

(18-3) Pricing Stock Issues

Benjamin Garcia's start-up business is succeeding, but he needs $200,000 in additional funding to fund continued growth. Benjamin and an angel investor agree the business is worth $800,000 and the angel has agreed to invest the $200,000 that is needed. Benjamin presently owns all 40,000 shares in his business. What is a fair price per share and how many additional shares must Benjamin sell to the angel? Because the stock will be sold directly to an investor, there is no spread; the other flotation costs are insignificant.

(18-4) New Stock Issue

Bynum and Crumpton, a small jewelry manufacturer, has been successful and has enjoyed a positive growth trend. Now B&C is planning to go public with an issue of common stock, and it faces the problem of setting an appropriate price for the stock. The company and its investment banks believe that the proper procedure is to conduct a valuation and select several similar firms with publicly traded common stock and to make relevant comparisons.

Several jewelry manufacturers are reasonably similar to B&C with respect to product mix, asset composition, and debt/equity proportions. Of these companies, Abercrombe Jewelers and Gunter Fashions are most similar. When analyzing the following data, assume that the most recent year has been reasonably "normal" in the sense that it was neither especially good nor especially bad in terms of sales, earnings, and free cash flows. Abercrombe is listed on the AMEX and Gunter on the NYSE, while B&C will be traded in the NASDAQ market.

Company Data	Abercrombe	Gunter	B&C
Shares outstanding	5 million	10 million	500,000
Price per share	$35.00	$47.00	NA
Earnings per share	$2.20	$3.13	$2.60
Free cash flow per share	$1.63	$2.54	$2.00
Book value per share	$16.00	$20.00	$18.00
Total assets	$115 million	$250 million	$11 million
Total debt	$35 million	$50 million	$2 million

a. B&C is a closely held corporation with 500,000 shares outstanding. Free cash flows have been low and in some years negative due to B&C's recent high sales growth rates, but as its expansion phase comes to an end, B&C's free cash flows should increase. B&C anticipates the following free cash flows over the next 5 years:

Year	1	2	3	4	5
FCF	$1,000,000	$1,050,000	$1,208,000	$1,329,000	$1,462,000

After Year 5, free cash flow growth will be stable at 7% per year. Currently, B&C has no nonoperating assets, and its WACC is 12%. Using the free cash flow valuation model (see Chapters 8 and 9), estimate B&C's intrinsic value of equity and intrinsic per share price.

b. Calculate debt to total assets, P/E, market to book, P/FCF, and ROE for Abercrombe, Gunter, and B&C. For calculations that require a price for B&C, use the per share price you obtained with the corporate valuation model in Part a.

c. Using Abercrombe's and Gunter's P/E, Market/Book, and Price/FCF ratios, calculate the range of prices for B&C's stock that would be consistent with these ratios. For example, if you multiply B&C's earnings per share by Abercrombe's P/E ratio you get a price. What range of prices do you get? How does this compare with the price you get using the corporate valuation model?

(18-5) Pricing Stock Issues in an IPO

Zang Industries has hired the investment banking firm of Eric, Schwartz, & Mann (ESM) to help it go public. Zang and ESM agree that Zang's current value of equity is $60 million. Zang currently has 4 million shares outstanding and will issue 1 million new shares. ESM charges a 7% spread. What is the correctly valued offer price? How much cash will Zang raise net of the spread?

CHALLENGING PROBLEMS 6–7

(18-6) Refunding Analysis

Jan Volk, financial manager of Green Sea Transport (GST), has been asked by her boss to review GST's outstanding debt issues for possible bond refunding. Five years ago, GST issued $40,000,000 of 11%, 25-year debt. The issue, with semiannual coupons, is currently callable at a premium of 11%, or $110 for each $1,000 par value bond. Flotation costs on this issue were 6%, or $2,400,000.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Volk believes that GST could issue 20-year debt today with a coupon rate of 8%. The firm has placed many issues in the capital markets during the last 10 years, and its debt flotation costs are currently estimated to be 4% of the issue's value. GST's federal-plus-state tax rate is 40%.

Help Volk conduct the refunding analysis by answering the following questions.

a. What is the total dollar call premium required to call the old issue? Is it tax deductible? What is the net after-tax cost of the call?
b. What is the dollar flotation cost on the new issue? Is it immediately tax deductible? What is the after-tax flotation cost?
c. What amounts of old-issue flotation costs have not been expensed? Can these deferred costs be expensed immediately if the old issue is refunded? What is the value of the tax savings?
d. What is the net after-tax cash outlay required to refund the old issue?
e. What is the semiannual tax savings that arises from amortizing the flotation costs on the new issue? What is the forgone semiannual tax savings on the old-issue flotation costs?
f. What is the semiannual after-tax interest savings that would result from the refunding?
g. Thus far, Volk has identified two future cash flows: (1) the net of new-issue flotation cost tax savings and old-issue flotation cost tax savings that are lost if refunding occurs and (2) after-tax interest savings. What is the sum of these two semiannual cash flows? What is the appropriate discount rate to apply to these future cash flows? What is their present value?
h. What is the NPV of refunding? Should GST refund now or wait until later?

(18-7) Refunding Analysis

Mullet Technologies is considering whether or not to refund a $75 million, 12% coupon, 30-year bond issue that was sold 5 years ago. It is amortizing $5 million of flotation costs on the 12% bonds over the issue's 30-year life. Mullet's investment banks have indicated that the company could sell a new 25-year issue at an interest rate of 10% in today's market. Neither they nor Mullet's management anticipate that interest rates will fall below 10% any time soon, but there is a chance that rates will increase.

A call premium of 12% would be required to retire the old bonds, and flotation costs on the new issue would amount to $5 million. Mullet's marginal federal-plus-state tax rate is 40%. The new bonds would be issued 1 month before the old bonds are called, with the proceeds being invested in short-term government securities returning 6% annually during the interim period.

a. Conduct a complete bond refunding analysis. What is the bond refunding's NPV?
b. What factors would influence Mullet's decision to refund now rather than later?

SPREADSHEET PROBLEMS

(18-8) Build a Model: IPO Terms

Start with the partial model in the file ***Ch18 P08 Build a Model.xlsx*** on the textbook's Web site. Lingadalli Corporation (LC) is considering an IPO. LC has 12 million shares of common stock owned by its founder and early investors. LC has no preferred stock, debt, or short-term investments. Based on its free cash flow projection, LC's intrinsic value of operations is $210 million. LC wants to raise $30 million (net of flotation costs) in net proceeds. The investment bank charges a 7% underwriting spread. All other costs

associated with the IPO are small enough to be neglected in this analysis and all shares sold in the IPO will be newly issued shares. Answer the following questions.

a. What is the intrinsic stock price per share before the IPO?
b. Given the target net proceeds, what amount of gross proceeds are required?
c. What is projected total value of LC immediately after the IPO? Based on the total amount paid by the shareholders purchasing new shares in the IPO, what percentage of the total post-IPO value do you think the new shareholders require to justify their stock purchases?
d. How many new shares must be sold in the IPO to provide the percentage of ownership required by the new shareholders? How many total shares will be outstanding after the IPO?
e. Based on number of new shares sold in the IPO and the total amount paid by the new shareholders, what is the offer price?
f. Based on total value of the company after the IPO and the total number of outstanding shares after the IPO, what is the intrinsic price per share after the IPO?
g. Compare the pre-IPO price, the offer price, and the post-IPO price. Explain why they are similar or different. (No calculations are required.)

(18-9) Build a Model: Bond Refunding

resource

Start with the partial model in the file ***Ch18 P09 Build a Model.xlsx*** on the textbook's Web site. Schumann Shoe Manufacturer is considering whether or not to refund a $70 million, 10% coupon, 30-year bond issue that was sold 8 years ago. It is amortizing $4.5 million of flotation costs on the 10% bonds over the issue's 30-year life. Schumann's investment bankers have indicated that the company could sell a new 22-year issue at an interest rate of 8% in today's market. Neither they nor Schumann's management anticipate that interest rates will fall below 6% anytime soon, but there is a chance that interest rates will increase.

a. Conduct a complete bond refunding analysis. What is the bond refunding's NPV?
b. At what interest rate on the new debt is the NPV of the refunding no longer positive?

MINI CASE

Randy's, a family-owned restaurant chain operating in Alabama, has grown to the point that expansion throughout the entire Southeast is feasible. The proposed expansion would require the firm to raise about $18.3 million in new capital. Because Randy's currently has a debt ratio of 50% and because family members already have all their personal wealth invested in the company, the family would like to sell common stock to the public to raise the $18.3 million. However, the family wants to retain voting control. You have been asked to brief family members on the issues involved by answering the following questions.

a. What agencies regulate securities markets?
b. How are start-up firms usually financed?
c. Differentiate between a private placement and a public offering.
d. Why would a company consider going public? What are some advantages and disadvantages?
e. What are the steps of an initial public offering?
f. What criteria are important in choosing an investment bank?
g. Would companies going public use a negotiated deal or a competitive bid?

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

h. Would the sale be on an underwritten or best efforts basis?
i. The estimated pre-IPO value of equity in the company is about $63 million and there are 4 million shares of existing shares of stock held by family members. The investment bank will charge a 7% spread, which is the difference between the price the new investor pays and the proceeds to the company. To net $18.3 million, what is the value of stock that must be sold? What is the total post-IPO value of equity? What percentage of this equity will the new investors require? How many shares will the new investors require? What is the estimated offer price per share?
j. What is a roadshow? What is book-building?
k. Describe the typical first-day return of an IPO and the long-term returns to IPO investors.
l. What are the direct and indirect costs of an IPO?
m. What are equity carve-outs?
n. Describe some ways other than an IPO that companies can use to raise funds from the capital markets.
o. What are some other investment banking activities? How did these increase investment banks' risk?
p. What is meant by "going private"? What are some advantages and disadvantages? What role do private equity funds play?
q. Under what conditions would a firm exercise a bond call provision?
r. Explain how firms manage the risk structure of their debt with project financing.

SELECTED ADDITIONAL CASES

The following cases from CengageCompose cover many of the concepts discussed in this chapter and are available at **http://compose.cengage.com.**

Klein-Brigham Series:
Case 21, "Sun Coast Savings Bank," illustrates the decision to go public; Case 22, "Precision Tool Company," emphasizes the investment banking process; Case 23, "Art Deco Reproductions, Inc.," focuses on the analysis of a rights offering; and Case 24, "Bay Area Telephone Company," Case 24A, "Shenandoah Power Company," and Case 24B, "Tucson Entertainment, Inc.," illustrate the bond refunding decision.

CHAPTER 19

Lease Financing

The Forty-Year-Old Virgin, starring Steve Carell, cost $26 million to produce but grossed over $177 million at box offices worldwide. That's a lot of money, but there is a 31-year-old Virgin making even more: Virgin Atlantic, the airline, turned 31 in 2015.

Virgin is privately held by Sir Richard Branson's Virgin Group (with Singapore Airlines owning a 49% share), so we don't know exactly how much money Virgin is making, but in mid-2009 Virgin placed an order for 10 Airbus A330-300 jet airliners that cost about $2.1 billion. Virgin purchased 6 of the jets and then immediately sold them to AerCap Holdings NV, a Dutch company specializing in leasing aircraft. AerCap then leased the jets back to Virgin. In addition, AerCap purchased 4 of the jets directly from Airbus and then leased them to Virgin. The bottom line is that Virgin didn't have to pony up $2.1 billion to get the 10 jets, but Virgin gets to operate the aircraft because it makes lease payments to AerCap.

Virgin had previously placed orders with Boeing, a U.S. company, for Boeing's 787 Dreamliner. Because Boeing experienced a series of production delays, Virgin turned to Airbus, which is owned by the European Aeronautic Defence and Space Company (EADS). EADS itself was formed in 2000 from a number of smaller companies at the encouragement of many European governments desiring a European company with the size and scope to be a major competitor in the global aviation and defense business.

Thus, the 10 Airbus jets will be produced in Europe by EADS, owned by the Dutch company AerCap, operated by the U.K. company Virgin Atlantic, and flown all over the world. As you read this chapter, think about the ways that leasing helps support global operations.

resource

The textbook's Web site contains an Excel *file that will guide you through the chapter's calculations. The file for this chapter is* ***Ch19 Tool Kit.xlsx****, and we encourage you to open the file and follow along as you read the chapter.*

Firms generally own fixed assets and report them on their balance sheets, but it is the use of assets that is important, not their ownership per se. One way to obtain the *use* of facilities and equipment is to buy them, but an alternative is to lease them. Prior to the 1950s, leasing was generally associated with real estate—land and buildings. Today, however, it is possible to lease virtually any kind of fixed asset, and currently over 50% of all new capital equipment and software is financed through lease arrangements.[1] In fact, the Equipment Leasing and Finance Foundation estimates that over $700 billion in equipment and software is acquired through leases each year.[2] Because leases are so frequently used by virtually all businesses, it is important for every manager to understand them.

19-1 Types of Leases

Lease transactions involve two parties: the **lessor**, who owns the property, and the **lessee**, who obtains use of the property in exchange for one or more lease, or rental, payments. (Note that the term *lessee* is pronounced "less-ee," not "lease-ee," and *lessor* is pronounced "less-or.") Because both parties must agree before a lease transaction can be completed, this chapter discusses leasing from the perspectives of both the lessor and the lessee.

Leasing takes several different forms, of which the five most important are: (1) operating leases; (2) financial, or capital, leases; (3) sale-and-leaseback arrangements; (4) combination leases; and (5) synthetic leases.

19-1a Operating Leases

Operating leases generally provide for both *financing* and *maintenance*. IBM was one of the pioneers of the operating lease contract, and computers and office copying machines—together with automobiles, trucks, and aircraft—are the primary types of equipment involved in operating leases. Ordinarily, operating leases require the lessor to maintain and service the leased equipment, and the cost of the maintenance is built into the lease payments.

Another important characteristic of operating leases is the fact that they are *not fully amortized*. In other words, the rental payments required under the lease contract are not sufficient for the lessor to recover the full cost of the asset. However, the lease contract is written for a period considerably shorter than the expected economic life of the asset, so the lessor can expect to recover all costs either by subsequent renewal payments, by releasing the asset to another lessee, or by selling the asset.

A final feature of operating leases is that they often contain a *cancelation clause* that gives the lessee the right to cancel the lease and return the asset before the expiration of the basic lease agreement. This is an important consideration to the lessee, for it means that the asset can be returned if it is rendered obsolete by technological developments or is no longer needed because of a change in the lessee's business.

---

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

19-1b Financial, or Capital, Leases

Financial leases, sometimes called **capital leases**, differ from operating leases in that they: (1) *do not* provide for maintenance service, (2) *are not* cancelable, and (3) *are* fully amortized (that is, the lessor receives rental payments equal to the full price of the leased equipment plus a return on invested capital). In a typical arrangement, the firm that will use the equipment (the lessee) selects the specific items it requires and negotiates the price with the manufacturer. The user firm then arranges to have a leasing company (the lessor) buy the equipment from the manufacturer and simultaneously executes a lease contract. The terms of the lease generally call for full amortization of the lessor's investment, plus a rate of return on the unamortized balance that is close to the percentage rate the lessee would have paid on a secured loan. For example, if the lessee had to pay 10% for a loan, then a rate of about 10% would be built into the lease contract.

The lessee is generally given an option to renew the lease at a reduced rate upon expiration of the basic lease. However, the basic lease usually cannot be canceled unless the lessor is paid in full. Also, the lessee generally pays the property taxes and insurance on the leased property. Because the lessor receives a return *after,* or *net of,* these payments, this type of lease is often called a "net, net" lease.

19-1c Sale-and-Leaseback Arrangements

Under a **sale-and-leaseback** arrangement, a firm that owns land, buildings, or equipment sells the property to another firm and simultaneously executes an agreement to lease the property back for a stated period under specific terms. The capital supplier could be an insurance company, a commercial bank, a specialized leasing company, the finance arm of an industrial firm, a limited partnership, or an individual investor. The sale-and-leaseback plan is an alternative to a mortgage.

Note that the seller immediately receives the purchase price put up by the buyer. At the same time, the seller-lessee retains the use of the property. The parallel to borrowing is carried over to the lease payment schedule. Under a mortgage loan arrangement, the lender would normally receive a series of equal payments just sufficient to amortize the loan and to provide a specified rate of return on the outstanding loan balance. Under a sale-and-leaseback arrangement, the lease payments are set up exactly the same way—the payments are just sufficient to return the full purchase price to the investor plus a stated return on the lessor's investment.

Sale-and-leaseback arrangements are almost the same as financial leases; the major difference is that the leased equipment is used, not new, and the lessor buys it from the user-lessee instead of a manufacturer or a distributor. A sale-and-leaseback is thus a special type of financial lease.

19-1d Combination Leases

Many lessors offer a wide variety of terms. Therefore, in practice leases often do not fit exactly into the operating lease or financial lease category but combine some features of each. Such leases are called **combination leases**. To illustrate, cancelation clauses are normally associated with operating leases, but many of today's financial leases also contain cancelation clauses. However, in financial leases these clauses generally include prepayment provisions whereby the lessee must make penalty payments sufficient to enable the lessor to recover the unamortized cost of the leased property.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

19-1e Synthetic Leases

A fifth type of lease, the *synthetic lease,* also should be mentioned. These leases were first used in the early 1990s, and they became very popular in the mid- to late-1990s when companies such as Enron and Tyco, as well as companies that did not engage in fraud, discovered that synthetic leases could be used to keep debt off their balance sheets. In a typical **synthetic lease**, a corporation that wanted to acquire an asset—generally real estate, with a very long life—with debt would first establish a **special purpose entity**, or **SPE**. The SPE would then obtain financing, typically 97% debt provided by a financial institution and 3% equity provided by a party other than the corporation itself.[3] The SPE would then use the funds to acquire the property, and the corporation would lease the asset from the SPE, generally for a term of 3 to 5 years but with an option to extend the lease, which the firm generally expected to exercise. Because of the relatively short term of the lease, it was deemed to be an operating lease and hence did not have to be capitalized and shown on the balance sheet.

A corporation that set up an SPE was required to do one of three things when the lease expired: (1) Pay off the SPE's 97% loan. (2) Refinance the loan at the current interest rate, if the lender was willing to refinance at all. (3) Sell the asset and make up any shortfall between the sale price and the amount of the loan. Thus, the corporate user was guaranteeing the loan, yet it did not have to show an obligation on its balance sheet.

Synthetic leases stayed under the radar until 2001. As we discuss in the next section, long-term leases must be capitalized and shown on the balance sheet. Synthetic leases were designed to get around this requirement, and neither the corporations that used them (such as Enron and Tyco) nor the accounting firms that approved them (such as Arthur Andersen) wanted anyone to look closely at them. However, the scandals of the early 2000s led security analysts, the SEC, banking regulators, the FASB, and even corporate boards of directors to begin seriously discussing SPEs and synthetic leases. Investors and bankers subjectively downgraded companies that made heavy use of them, and boards of directors began to tell their CFOs to stop using them and to close down the ones that existed. In 2003, the FASB put in place rules that require companies to report on their balance sheets most special purpose entities and synthetic leases of the type Enron abused, limiting management's opportunity to hide these transactions from shareholders.

SELF-TEST

Who are the two parties to a lease transaction?

What is the difference between an operating lease and a financial, or capital, lease?

What is a sale-and-leaseback transaction?

What is a combination lease?

What is a synthetic lease?

[3]Enron's CFO, Andy Fastow, and other insiders provided the equity for many of Enron's SPEs. Also, a number of Merrill Lynch's executives provided SPE equity, allegedly to enable Merrill Lynch to obtain profitable investment banking deals. The very fact that SPEs are so well suited to conceal what is going on helped those who used them engage in shady deals that would have at least raised eyebrows had they been disclosed. In fact, Fastow pled guilty to two counts of conspiracy in connection to Enron's accounting fraud and ultimate bankruptcy. For more on this subject, see W. R. Pollert and E. J. Glickman, "Synthetic Leases under Fire," at **www.strategicfinancemag.com,** October 2002.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

19-2 Tax Effects

The full amount of the lease payments is a tax-deductible expense for the lessee *provided the Internal Revenue Service agrees that a particular contract is a genuine lease and not simply a loan called a lease.* This makes it important that a lease contract be written in a form acceptable to the IRS. A lease that complies with all IRS requirements is called a **guideline**, or **tax-oriented, lease**, and the tax benefits of ownership (depreciation and any investment tax credits) belong to the lessor. The main provisions of the tax guidelines are as follows:

1. The lease term (including any extensions or renewals at a fixed rental rate) must not exceed 80% of the estimated useful life of the equipment at the commencement of the lease transaction. Thus, an asset with a 10-year life can be leased for no more than 8 years. Further, the remaining useful life must not be less than 1 year. Note that an asset's expected useful life is normally much longer than its MACRS depreciation class life.
2. The equipment's estimated residual value (in real dollars without any price increase due to inflation) at the expiration of the lease must be at least 20% of its value at the start of the lease. This requirement can have the effect of limiting the maximum lease term.
3. Neither the lessee nor any related party can have the right to purchase the property at a predetermined fixed price. However, the lessee can be given an option to buy the asset at its fair market value.
4. Neither the lessee nor any related party can pay or guarantee payment of any part of the price of the leased equipment. Simply put, the lessee cannot make any investment in the equipment other than through the lease payments.
5. The leased equipment must not be "limited use" property, defined as equipment that can be used only by the lessee or a related party at the end of the lease.

The reason for the IRS's concern about lease terms is that, without restrictions, a company could set up a "lease" transaction calling for very rapid payments, which would be tax deductible. The effect would be to depreciate the equipment over a much shorter period than its MACRS class life. For example, suppose a firm planned to acquire a $2 million computer that had a 3-year MACRS class life. The annual depreciation allowances would be $666,600 in Year 1, $889,000 in Year 2, $296,200 in Year 3, and $148,200 in Year 4. If the firm were in the 40% federal-plus-state tax bracket, the depreciation would provide a tax savings of $266,640 in Year 1, $355,600 in Year 2, $118,480 in Year 3, and $59,280 in Year 4, for a total savings of $800,000. At a 6% discount rate, the present value of these tax savings would be $714,463.

Now suppose the firm could acquire the computer through a 1-year lease arrangement with a leasing company for a payment of $2 million, with a $1 purchase option. If the $2 million payment were treated as a lease payment, it would be fully deductible, so it would provide a tax savings of $0.4(\$2{,}000{,}000) = \$800{,}000$ versus a present value of only $714,463 for the depreciation shelters. Thus, the lease payment and the depreciation would both provide the same total amount of tax savings (40% of $2,000,000, or $800,000), but the savings would come in faster with the 1-year lease, giving it a higher present value. Therefore, if just any type of contract could be called a lease and given tax treatment as a lease, then the timing of the tax shelters could be speeded up as compared with ownership depreciation tax shelters. This speedup would benefit companies, but it would be costly to the government. For this reason, the IRS has established the rules just described for defining a lease for tax purposes.

Even though leasing can be used only within limits to speed up the effective depreciation schedule, there are still times when very substantial tax benefits can be derived from a leasing arrangement. For example, if a firm has incurred losses and hence has no current tax liabilities, then its depreciation shelters are not very useful. In this case, a leasing company set up by profitable companies such as GE or Philip Morris can buy the equipment, receive the depreciation shelters, and then share these benefits with the lessee by charging lower lease payments. This will be discussed in detail later in the chapter, but the point now is that if firms are to obtain tax benefits from leasing, the lease contract must be written in a manner that will qualify it as a true lease under IRS guidelines. If there is any question about the legal status of the contract, the financial manager must be sure to have the firm's lawyers and accountants check the latest IRS regulations.

Note that a lease that does not meet the tax guidelines is called a **non-tax-oriented lease**. For this type of lease, the lessee: (1) is the effective owner of the leased property, (2) can depreciate it for tax purposes, and (3) can deduct only the interest portion of each lease payment.

SELF-TEST

What is the difference between a tax-oriented lease and a non-tax-oriented lease?

What are some lease provisions that would cause a lease to be classified as a non-tax-oriented lease?

Why does the IRS place limits on lease provisions?

19-3 Financial Statement Effects

Under certain conditions, neither the leased assets nor the liabilities under the lease contract appear directly on the firm's balance sheet. For this reason, leasing is often called **off-balance sheet financing**. This point is illustrated in Table 19-1 by the balance sheets of two hypothetical firms, B (for "borrow") and L (for "lease"). Initially, the balance sheets of both firms are identical, and they both have debt ratios of 50%. Next, each firm decides to acquire a fixed asset costing $100. Firm B borrows $100 and buys the asset, so both an asset and a liability go on its balance sheet, and its debt ratio rises from 50% to 75%. Firm L leases the equipment. The lease may call for fixed charges as high as or even higher than the loan, and the obligations assumed under the lease may be equally or more dangerous from the standpoint of potential bankruptcy, but the firm's debt ratio remains at only 50%.

To correct this problem, the Financial Accounting Standards Board (FASB) issued **FASB Statement 13**, which requires that, for an unqualified audit report, firms entering into financial (or capital) leases must restate their balance sheets and report the leased asset as a fixed asset and the present value of the future lease payments as a liability. This process is called **capitalizing the lease**, and its net effect is to cause Firms B and L to have similar balance sheets—both of which will, in essence, resemble the one shown for Firm B.[4]

The logic behind Statement 13 is as follows: If a firm signs a financial lease contract, its obligation to make lease payments is just as binding as if it had signed a loan agreement—the failure to make lease payments can bankrupt a firm just as fast as the

[4]FASB Statement 13, "Accounting for Leases," spells out in detail both the conditions under which the lease must be capitalized and the procedures for capitalizing it. See also chapter 4 of Schallheim's *Lease or Buy?* (cited in footnote 1) for more on the accounting treatment of leases.

TABLE 19-1
Balance Sheet Effects of Leasing

Panel A: Before Asset Increase							
Firms B and L							
Current assets	$ 50	Debt	$ 50				
Fixed assets	50	Equity	50				
	$100		$100				
Debt/assets ratio:			50%				
Panel B: After Asset Increase							
Firm B, Which Borrows and Buys				**Firm L, Which Leases**			
Current assets	$ 50	Debt	$150	Current assets	$ 50	Debt	$ 50
Fixed assets	150	Equity	50	Fixed assets	50	Equity	50
	$200		$200		$100		$100
Debt/assets ratio:			75%				50%

failure to make principal and interest payments on a loan. Therefore, for all intents and purposes, a financial lease is identical to a loan.[5] This being the case, if a firm signs a financial lease agreement, then the effect is to raise its true debt ratio, and hence its true capital structure is changed. Therefore, if the firm had previously established a target capital structure and if there is no reason to think the optimal capital structure has changed, then lease financing requires additional equity support, just as debt financing does.

If disclosure of the lease in our Table 19-1 example were not made, then Firm L's investors could be deceived into thinking its financial position is stronger than it really is. Thus, even before FASB Statement 13 was issued, firms were required to disclose the existence of long-term leases in footnotes to their financial statements. At that time, it was debated as to whether or not investors recognized fully the impact of leases and, in effect, would see that Firms B and L were in essentially the same financial position. Some people argued that leases were not fully recognized, even by sophisticated investors. If this were the case, then leasing could alter the capital structure decision in a significant manner—a firm could increase its true leverage through a lease arrangement, and this procedure would have a smaller effect on its cost of conventional debt, r_d, and on its cost of equity, r_s, than if it had borrowed directly and reflected this fact on its balance sheet. These benefits of leasing would accrue to existing investors at the expense of new investors, who would be deceived because the firm's balance sheet did not reflect its true financial leverage.

[5]There are, however, certain legal differences between loans and leases. In the event of liquidation in bankruptcy, a lessor is entitled to take possession of the leased asset, and if the value of the asset is less than the required payments under the lease, the lessor can enter a claim (as a general creditor) for 1 year's lease payments. Also, after bankruptcy has been declared but before the case has been resolved, lease payments may be continued, whereas all payments on debts are generally stopped. In a reorganization, the lessor receives the asset plus 3 years' lease payments if needed to cover the value of the lease. The lender under a secured loan arrangement has a security interest in the asset; this means that, if the asset is sold, then the lender will be given the proceeds and the full unsatisfied portion of the lender's claim will be treated as a general creditor obligation. It is not possible to state, as a general rule, whether a supplier of capital is in a stronger position as a secured creditor or as a lessor. However, in certain situations, lessors may bear less risk than secured lenders if financial distress occurs.

The question of whether investors were truly deceived was debated but never resolved. Those who believed strongly in efficient markets thought investors were not deceived and that footnotes were sufficient, while those who questioned market efficiency thought all leases should be capitalized. Statement 13 represents a compromise between these two positions, though one that is tilted heavily toward those who favor capitalization.

A lease is classified as a capital lease—and hence must be capitalized and shown directly on the balance sheet—if one or more of the following conditions exist.

1. Under the terms of the lease, ownership of the property is effectively transferred from the lessor to the lessee.
2. The lessee can purchase the property at less than its true market value when the lease expires.
3. The lease runs for a period equal to or greater than 75% of the asset's life. Thus, if an asset has a 10-year life and the lease is written for 8 years, the lease must be capitalized.
4. The present value of the lease payments is equal to or greater than 90% of the initial value of the asset.[6]

These rules, together with strong footnote disclosure rules for operating leases, were supposed to be sufficient to ensure that no one would be fooled by lease financing. Thus, leases should be regarded as debt for capital structure purposes, and they should have the same effects as debt on r_d and r_s. Therefore, leasing is not likely to permit a firm to use more financial leverage than could be obtained with conventional debt.

SELF-TEST

Why is lease financing sometimes referred to as off-balance sheet financing?

What is the intent of FASB Statement 13?

What is the difference in the balance sheet treatment of a lease that is capitalized versus one that is not?

Off-Balance Sheet Financing: Is It Going to Disappear?

There is currently (early 2015) a movement to standardize global accounting regulations, with the IASB (International Accounting Standards Board) and the FASB working toward this goal. One element of any agreement will be the treatment of leases. It appears likely that the FASB and IASB will require all leases to be capitalized, even those that are now classified as operating leases. In fact, they have agreed that the leases should be shown on the balance sheets, but they are still debating how to recognize the lease-associated expenses on the income statements.

This could have a huge impact on many companies' financial statements. For example, Credit Suisse estimated that the S&P 500 firms use about $369 billion in assets that are in the form of operating leases. As such, these are not shown as either assets or liabilities and instead are off the balance sheets. Putting these leases on the balance sheets by capitalizing them would boost the average liabilities by about 2%, but the impact would be much higher for some companies. This might be painful for businesses, but it certainly would help investors identify a company's obligations and liabilities.

[6]The discount rate used to calculate the present value of the lease payments must be the lower of: (1) the rate used by the lessor to establish the lease payments (this rate is discussed later in the chapter) or (2) the rate of interest that the lessee would have to pay for new debt with a maturity equal to that of the lease. Also, note that any maintenance payments embedded in the lease payment must be stripped out prior to checking this condition.

19-4 Evaluation by the Lessee

resource
*See **Ch19 Tool Kit.xlsx** on the textbook's Web site for all calculations.*

Leases are evaluated by both the lessee and the lessor. The lessee must determine whether leasing an asset is less costly than buying it, and the lessor must decide whether the lease payments provide a satisfactory return on the capital invested in the leased asset. This section focuses on the lessee's analysis.

In the typical case, the events leading to a lease arrangement follow the sequence described below. Note that a degree of uncertainty exists regarding the theoretically correct way to evaluate lease-versus-purchase decisions, and some very complex decision models have been developed to aid in the analysis. However, the simple analysis given here leads to the correct decision in all the cases we have ever encountered.

resource
*See **Web Extension 19A** on the textbook's Web site for more information on such feedback effects.*

1. When the firm decides to acquire a particular building or piece of equipment, the decision is based on regular capital budgeting procedures. Whether or not to acquire the asset is *not* part of the typical lease analysis—in a lease analysis, we are concerned simply with whether to obtain the use of the machine by lease or by purchase. Thus, for the lessee, the lease decision is typically just a financing decision. However, if the effective cost of capital obtained by leasing is substantially lower than the cost of debt, then the cost of capital used in the capital budgeting decision would have to be recalculated, and perhaps projects formerly deemed unacceptable might become acceptable. Such feedback effects usually are very small and can safely be ignored.
2. Once the firm has decided to acquire the asset, the next question is how to finance it. Well-run businesses do not have excess cash lying around, so capital to finance new assets must be obtained from some source.
3. Funds to purchase the asset could be obtained from internally generated cash flows, by borrowing, or by selling new equity. Alternatively, the asset could be leased. Because of the capitalization/disclosure provision for leases, leasing normally has the same capital structure effect as borrowing.
4. As indicated earlier, a lease is comparable to a loan in the sense that the firm is required to make a specified series of payments, and a failure to meet these payments could result in bankruptcy. If a company has a target capital structure, then \$1 of lease financing displaces \$1 of debt financing. Thus, the most appropriate comparison is lease financing versus debt financing. Note that the analysis should compare the cost of leasing with the cost of debt financing *regardless* of how the asset purchase is actually financed. The asset may be purchased with available cash or with cash raised by issuing stock, but because leasing is a substitute for debt financing and has the same capital structure effect, the appropriate comparison would still be with debt financing.

resource
*See **Ch19 Tool Kit.xlsx** on the textbook's Web site for this analysis.*

To illustrate the basic elements of lease analysis, consider this simplified example. (See ***Ch19 Tool Kit.xlsx*** on the textbook's Web site for this analysis.) The Thompson-Grammatikos Company (TGC) needs a 2-year asset that costs \$100 million, and the company must choose between leasing and buying the asset. TGC's tax rate is 40%. If the asset is purchased, the bank would lend TGC the \$100 million at a rate of 10% on a 2-year, simple interest loan. Thus, the firm would have to pay the bank \$10 million in interest at the end of each year *and* return the \$100 million of principal at the end of Year 2. However, the interest expense is deductible, so the tax shelter is T(Interest expense) = 0.4(\$10 million) = \$4 million. For simplicity, assume that: (1) TGC could depreciate the asset over 2 years for tax purposes by the straight-line method if it is purchased, resulting in tax depreciation of \$50 million and tax savings of T(Depreciation) = 0.4(\$50) = \$20 million in each year; and (2) the asset's value at the end of 2 years will be \$0.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Alternatively, TGC could lease the asset under a guideline lease (by a special IRS ruling) for 2 years for a payment of $55 million at the end of each year. These payments are deductible, so the tax shelter is T(Lease payment) = 0.4($55 million) = $22 million.

The analysis for the lease-versus-borrow decision consists of: (1) estimating the cash flows associated with borrowing and buying the asset—that is, the flows associated with debt financing; (2) estimating the cash flows associated with leasing the asset; and (3) comparing the two financing methods to determine which is preferable. Figure 19-1 reports the borrow-and-buy flows, set up to produce a cash flow time line for owning option.

The net cash flow for owning is zero in Year 0, positive in Year 1, and negative in Year 2. The operating cash flows are not shown, but they must, of course, have a PV greater than the PV of the financing costs or else TGC would not want to acquire the asset. Because the operating cash flows will be the same regardless of whether the asset is leased or purchased, they can be ignored.

Figure 19-1 also shows the cash flows associated with leasing. Note that the two sets of cash flows reflect the tax deductibility of interest and depreciation if the asset is purchased or the deductibility of lease payments if it is leased. Thus, the net cash flows include the tax savings from these items.[7]

FIGURE 19-1
Analysis of the TGC Lease-versus-Buy Decision (Millions of Dollars)

	A	B	C	D	E
83	**Cost of Owning**			Year	
84			0	1	2
85	Equipment cost		–$100		
86	Loan amount		$100		
87	Interest expense			–$10	–$10
88	Tax savings from interest			$4	$4
89	Principal repayment				–$100

94	**Cost of Leasing**			Year	
95			0	1	2
96	Lease payment			–$55	–$55
97	Tax savings from lease			$22	$22
98	Net cash flow (NCF)		$0	–$33	–$33
99					
100	PV of leasing NCF @ 6%		–$60.50		
101	**Net advantage to leasing (NAL)**				
102			NAL =PV of leasing – PV of owning		$2.83

Source: See the file ***Ch19 Tool Kit.xlsx***. Numbers are reported as rounded values for clarity, but are calculated using *Excel*'s full precision. Thus, intermediate calculations using the figure's rounded values will be inexact.

[7]If the lease had not met IRS guidelines, then ownership would effectively reside with the lessee, and TGC would depreciate the asset for tax purposes whether it was leased or purchased. However, only the implied interest portion of the lease payment would be tax deductible. Thus, the analysis for a nonguideline lease would consist of simply comparing the after-tax financing flows on the loan with the after-tax lease payment stream.

resource

*See **Ch19 Tool Kit.xlsx** on the textbook's Web site for all calculations.*

To compare the cost streams of buying versus leasing, we must put them on a present value basis. As we explain later, the correct discount rate is the after-tax cost of debt, which for TGC is $10\%(1 - 0.4) = 6.0\%$. Applying this rate, we find the present value of the ownership cash flows is −$63.33 million versus a present value of leasing cash flows of −$60.50 million.

We define the **net advantage to leasing (NAL)** as follows:

$$\text{NAL} = \text{PV of leasing} - \text{PV of owning} \quad \textbf{(19-1)}$$

For TGC, the NAL is $-\$60.50 - (-\$63.33) = \$2.83$ million. The PV of owning is more negative than the PV of leasing, so leasing is preferable.

Now we examine a more realistic example, one from the Anderson Company, which is conducting a lease analysis on some assembly line equipment it will procure during the coming year. (See ***Ch19 Tool Kit.xlsx*** on the textbook's Web site for this analysis.) The following data have been collected:

1. Anderson plans to acquire automated assembly line equipment with a 10-year life at a cost of $10 million, delivered and installed. However, Anderson plans to use the equipment for only 5 years and then discontinue the product line.
2. Anderson can borrow the required $10 million at a pre-tax cost of 10%.
3. The equipment's estimated scrap value is $50,000 after 10 years of use, but its estimated salvage value after only 5 years of use is $2,000,000. Thus, if Anderson buys the equipment, it would expect to receive $2,000,000 before taxes when the equipment is sold in 5 years. In leasing, the asset's value at the end of the lease is called its **residual value**.
4. Anderson can lease the equipment for 5 years for an annual rental charge of $2,600,000, payable at the beginning of each year, but the lessor will own the equipment upon the expiration of the lease. (The lease payment schedule is established by the potential lessor, as described in the next section, and Anderson can accept it, reject it, or negotiate modifications.)
5. The lease contract stipulates that the lessor will maintain the equipment at no additional charge to Anderson. However, if Anderson borrows and buys, it will have to bear the cost of maintenance, which will be done by the equipment manufacturer at a fixed contract rate of $500,000 per year, payable at the beginning of each year.
6. The equipment falls in the MACRS 5-year class, Anderson's marginal tax rate is 35%, and the lease qualifies as a guideline lease.

Figure 19-2 shows the steps involved in the analysis. Part A of the table is devoted to the costs of borrowing and buying. The company borrows $10 million and uses it to pay for the equipment, so these two items net out to zero and thus are not shown in the figure. Then, the company makes the *after-tax* payments shown in Line 1. In Year 1, the after-tax interest charge is $0.10(\$10 \text{ million})(1 - 0.35) = \$650{,}000$, and other payments are calculated similarly. The $10 million loan is repaid at the end of Year 5. Line 2 shows the maintenance cost. Line 3 gives the maintenance tax savings. Line 4 contains the annual depreciation tax savings, which are the depreciation expenses multiplied by the tax rate. The notes to Figure 19-2 explain the depreciation calculation. Lines 5 and 6 contain the residual (or salvage) value cash flows. The tax is on the excess of the residual value over the asset's book value, not on the full residual value. Line 7 contains the net cash flows, and Line 8 shows the net present value of these flows discounted at 6.5%, which is negative.

158								
159	12. PV of leasing CF @ 6.5%		−$7,480					
160	**Part C: Net advantage to leasing (NAL)**							
161	13. NAL = PV of leasing − PV of owning =				$54			

Source: See the file ***Ch19 Tool Kit.xlsx***. Numbers are reported as rounded values for clarity, but are calculated using *Excel*'s full precision. Thus, intermediate calculations using the figure's rounded values will be inexact.

Notes:

1. The after-tax loan payments consist of after-tax interest for Years 1–4 and after-tax interest plus the principal amount in Year 5.
2. The net cash flows shown in Lines 7 and 11 are discounted at the lessee's after-tax cost of debt, 6.5%.
3. The MACRS depreciation allowances are 0.20, 0.32, 0.192, 0.1152, and 0.1152 in Years 1 through 5, respectively. Thus, the depreciation expense is 0.20($10,000) = $2,000 in Year 1, and so on. The depreciation tax savings in each year is 0.35(Depreciation).
4. The residual value is $2,000, while the book value is $576. Thus, Anderson would have to pay 0.35($2,000 − $576) = $498.4 in taxes, producing a net after-tax residual value of $2,000 − $498.4 = $1,501.6. These amounts are shown in Lines 5 and 6 in the cost-of-owning analysis.
5. Maintenance is shown at the beginning of the year to reflect cash that is set aside for routine maintenance throughout the year.

Part B of Figure 19-2 analyzes the lease. The lease payments, shown in Line 9, are $2,600,000 per year; this rate, which includes maintenance, was established by the prospective lessor and offered to Anderson Equipment. If Anderson accepts the lease then the full amount will be a deductible expense, so the annual tax savings, shown in Line 10, are 0.35(Lease payment) = 0.35($2,600,000) = $910,000. Thus, the after-tax cost of the lease payment is Lease payment − Tax savings = $2,600,000 − $910,000 = $1,690,000. This amount is shown in Line 11 for Years 0 through 4.

The next step is to compare leasing versus owning. However, we must first put the annual cash flows of leasing and borrowing on a common basis. This requires converting them to present values, which brings up the question of the proper rate at which to discount the costs. Because leasing is a substitute for debt, most analysts recommend that the company's cost of debt be used, and this rate seems reasonable in our example. Moreover, because the cash flows are after taxes, *we should use the after-tax cost of debt,* which is 10%(1 − T) = 10%(0.65) = 6.5%. Accordingly, we discount the net cash flows

resource

in Lines 7 and 11 using a rate of 6.5%. The resulting present values are −$7,480,000 for the present value of leasing and −$7,534,000 for the present value of owning. The net advantage to leasing is about $54 thousand (ignoring rounding differences):

$$\begin{aligned} \text{NAL} &= \text{PV of leasing} - \text{PV of owning} \\ &= -\$7{,}480{,}000 - (-\$7{,}534{,}000) \\ &= \$54{,}000 \end{aligned}$$

Owning is more costly than leasing, so the NAL is positive. Therefore, Anderson should lease the equipment.[8]

In this example, Anderson did not plan on using the equipment beyond Year 5. But if Anderson instead had planned on using the equipment after Year 5, the analysis would be modified. For example, suppose Anderson planned on using the equipment for 10 years and the lease allowed Anderson to purchase the equipment at the residual value. First, how do we modify the cash flows due to owning? Lines 5 and 6 (for residual value and tax on residual value) in Figure 19-2 will be zero at Year 5, because Anderson will not sell the equipment then.[9] However, there will be the additional remaining year of depreciation tax savings in Line 4 for Year 6. There will be no entries for Years 6–10 for Line 1, the after-tax loan payments, because the loan is completely repaid at Year 5. Also, there will be no incremental maintenance costs and tax savings in Lines 2 and 3 for Years 6–10, because Anderson will have to perform its own maintenance on the equipment in those years whether it initially purchases the equipment or whether it leases the equipment for 5 years and then purchases it. Either way, Anderson will own the equipment in Years 6–10 and must pay for its own maintenance.

Second, how do we modify the cash flows if Anderson leases the equipment and then purchases it at Year 5? There will be a negative cash flow at Year 5 reflecting the purchase. Because the equipment was originally classified with a MACRS 5-year life, Anderson will be allowed to depreciate the purchased equipment (even though it is not new) with a MACRS 5-year life. Therefore, in Years 6–10, there will be after-tax savings due to depreciation.[10] Given the modified cash flows, we can calculate the NAL just as we did in Figure 19-2.

resource

The percentage approach is discussed in ***Web Extension 19B*** *on the textbook's Web site.*

In this section, we focused on the dollar cost of leasing versus borrowing and buying, which is analogous to the NPV method used in capital budgeting. A second method that lessees can use to evaluate leases focuses on the percentage cost of leasing and is analogous to the IRR method used in capital budgeting.

SELF-TEST

Explain how the cash flows are structured in order to estimate the net advantage to leasing.

What discount rate should be used to evaluate a lease? Why?

Define the term net advantage to leasing *(NAL).*

[8]The more complicated methods that exist for analyzing leasing generally focus on the issue of what discount rate should be used to discount the cash flows—especially the residual value, because its risk might be different from the risk of the other cash flows. For more on residual value risk, see chapter 8 of Schallheim's *Lease or Buy?* (cited in footnote 1).

[9]There might be a salvage value in Line 5 at Year 10 (and a corresponding tax adjustment in Line 6) if the equipment is not completely worn out or obsolete.

[10]There will also be an after-tax cash flow at Year 10 that depends on the salvage value of the equipment at that date.

19-5 Evaluation by the Lessor

Thus far, we have considered leasing only from the lessee's viewpoint. It is also useful to analyze the transaction as the lessor sees it: Is the lease a good investment for the party who must put up the money? The lessor will generally be a specialized leasing company, a bank or bank affiliate, an individual or group of individuals organized as a limited partnership or limited liability corporation, or a manufacturer such as IBM or GM that uses leasing as a sales tool. The specialized leasing companies are often owned by profitable companies such as General Electric, which owns General Electric Capital, the largest leasing company in the world. Investment banking houses such as Goldman Sachs also set up and/or work with specialized leasing companies, where brokerage clients' money is made available to leasing customers in deals that permit the investors to share in tax shelters provided by leases.

Any potential lessor needs to know the rate of return on the capital invested in the lease, and this information is also useful to the prospective lessee: Lease terms on large leases are generally negotiated, so the lessee should know what return the lessor is earning. The lessor's analysis involves: (1) determining the net cash outlay, which is usually the invoice price of the leased equipment less any lease payments made in advance; (2) determining the periodic cash inflows, which consist of the lease payments minus both income taxes and any maintenance expense the lessor must bear; (3) estimating the after-tax residual value of the property when the lease expires; and (4) determining whether the rate of return on the lease exceeds the lessor's opportunity cost of capital or, equivalently, whether the NPV of the lease exceeds zero.

19-5a Analysis by the Lessor

resource

*See **Ch19 Tool Kit.xlsx** on the textbook's Web site for all calculations.*

To illustrate the lessor's analysis, we assume the same facts as for the Anderson Company lease, plus the following: (1) The potential lessor is a wealthy individual whose current income is in the form of interest and whose marginal federal-plus-state income tax rate, T, is 40%. (2) The investor can buy 5-year bonds that have a 9% yield to maturity, providing an after-tax yield of $(9\%)(1 - T) = (9\%)(0.6) = 5.4\%$. This is the after-tax return the investor can obtain on alternative investments of similar risk. (3) The before-tax residual value is $2,000,000. Because the asset will be depreciated to a book value of $600,000 at the end of the 5-year lease, $1,400,000 of this $2 million will be taxable at the 40% rate by the depreciation recapture rule, so the lessor can expect to receive $\$2{,}000{,}000 - 0.4(\$1{,}400{,}000) = \$1{,}440{,}000$ after taxes from the sale of the equipment after the lease expires.

The lessor's cash flows are developed in Figure 19-3. Here we see that the lease as an investment has a net present value of $81,091. On a present value basis, the investor who invests in the lease rather than in the 9% bonds (5.4% after taxes) is better off by $81,091, indicating that he or she should be willing to write the lease. As we saw earlier, the lease is also advantageous to Anderson Company, so the transaction should be completed.

The investor can also calculate the lease investment's internal rate of return based on the net cash flows shown in Line 9 of Figure 19-3. The IRR of the lease, which is that discount rate that forces the NPV of the lease to zero, is 5.8%. Thus, the lease provides a 5.8% after-tax return to this 40% tax rate investor, which exceeds the 5.4% after-tax return on 9% bonds. So, using either the IRR or the NPV method, the lease would appear to be a satisfactory investment.[11]

[11]Note that the lease investment is actually slightly more risky than the alternative bond investment because the residual value cash flow is less certain than a principal repayment. Thus, the lessor might require an expected return somewhat above the 5.4% promised on a bond investment.

Notes:

[a] Depreciation tax savings = Depreciation × (Tax rate).
[b] (Residual value − Book value) × (Tax rate).

19-5b Setting the Lease Payment

So far we have evaluated leases assuming that the lease payments have already been specified. However, in large leases the parties generally sit down and work out an agreement on the size of the lease payments, with these payments being set so as to provide the lessor with some specific rate of return. In situations in which the lease terms are not negotiated, which is often the case for small leases, the lessor must still go through the same type of analysis, setting terms that provide a target rate of return and then offering these terms to the potential lessee on a take-it-or-leave-it basis.

To illustrate all this, suppose the potential lessor described earlier, after examining other alternative investment opportunities, decides that the 5.4% after-tax bond return is too low to use for evaluating the lease and that the required after-tax return on the lease should be 6.0%. What lease payment schedule would provide this return?

To answer this question, note again that Figure 19-3 contains the lessor's cash flow analysis. We used the *Excel* Goal Seek function to set the lessor's IRR equal to 6% by changing the lease payment; see the analysis in ***Ch19 Tool Kit.xlsx.*** We found that the lessor must set the lease payment at $2,621,278 to obtain an after-tax rate of return of 6.0%. If this lease payment is not acceptable to the lessee, Anderson Company, then it may not be possible to strike a deal. Naturally, competition among leasing companies forces lessors to build market-related returns into their lease payment schedules.[12]

[12]For a discussion of realized returns on lease contracts, see Ronald C. Lease, John J. McConnell, and James S. Schallheim, "Realized Returns and the Default and Prepayment Experience of Financial Leasing Contracts," *Financial Management*, Summer 1990, pp. 11–20.

If the inputs to the lessee and the lessor are identical, then a positive NAL to the lessee implies an equal but negative NPV to the lessor. However, *conditions are often such that leasing can provide net benefits to both parties. This situation arises because of differentials in taxes, in borrowing rates, in estimated residual values, or in the ability to bear the residual value risk.* We will explore these issues in detail in the next section.

Note that the lessor can, under certain conditions, increase the return on the lease by borrowing some of the funds used to purchase the leased asset. Such a lease is called a **leveraged lease**. Whether or not a lease is leveraged has no effect on the lessee's analysis, but it can have a significant effect on the cash flows to the lessor and hence on the lessor's expected rate of return.

resource

We discuss leveraged leases in more detail in ***Web Extension 19C*** *on the textbook's Web site.*

SELF-TEST

What discount rate is used in a lessor's NPV analysis?

Under what conditions will the lessor's NPV be the negative of the lessee's NAL?

19-6 Other Issues in Lease Analysis

The basic methods of analysis used by lessees and lessors were presented in the previous sections. However, some other issues warrant discussion.[13]

19-6a Estimated Residual Value

It is important to note that the lessor owns the property upon expiration of a lease, so the lessor has claim to the asset's residual value. Superficially, it would appear that if residual values are expected to be large, then owning would have an advantage over leasing. However, this apparent advantage does not hold up. If expected residual values are large—as they may be under inflation for certain types of equipment and also if real estate is involved—then competition between leasing companies and other financing sources, as well as competition among leasing companies themselves, will force leasing rates down to the point where potential residual values are fully recognized in the lease contract. Thus, the existence of large residual values is not likely to result in materially higher costs for leasing.

19-6b Increased Credit Availability

As noted earlier, leasing is sometimes said to be advantageous for firms that are seeking to increase their financial leverage. First, it is sometimes argued that firms can obtain more money, and for longer terms, under a lease arrangement than under a loan secured by a specific piece of equipment. Second, because some leases do not appear on the balance sheet, lease financing has been said to give the firm a stronger appearance in a *superficial* credit analysis and thus to permit the firm to use more leverage than would be possible if it did not lease.

There may be some truth to these claims for smaller firms. However, because firms are required to capitalize financial leases and to report them on their balance sheets, this point is of questionable validity for any firm large enough to have audited financial statements.

[13]For a description of lease analysis in practice as well as a comprehensive bibliography of the leasing literature, see Tarun K. Mukherjee, "A Survey of Corporate Leasing Analysis," *Financial Management*, Autumn 1991, pp. 96–107.

What You Don't Know Can Hurt You!

A leasing decision seems to be pretty straightforward, at least from a financial perspective: Calculate the NAL for the lease and undertake it if the NAL is positive. Right? But tracking down all the financial implications from lease contract provisions can be difficult, requiring the lessee to make assumptions about future costs that are not explicitly spelled out in the lease contract. For example, consider the purchase option embedded in the lease that Rojacks Food Stores undertook with GE Capital for restaurant equipment. Upon expiration, the lease allowed Rojacks either to return the equipment or purchase it at the current market value. When the lease expired, GE set a purchase price that was much higher than Rojacks expected. Rojacks needed the equipment for its day-to-day operations, so it couldn't just return the equipment without disrupting its business. Ultimately, Rojacks hired an independent appraiser for the equipment and negotiated a lower purchase price—but without the appraiser, Rojacks would have been stuck with the price GE decided to set for the equipment. The Rojacks–GE situation isn't that unusual. Lessors often use high expected residual values or high expected penalties to offset low lease payments. In addition, some contracts may require that: (1) all of the equipment covered under a lease must either be purchased or returned in its entirety, (2) equipment that is moved must be purchased, (3) large fees must be paid even for minor damage or missing parts, and/or (4) equipment must be returned in its original packaging. These conditions impose costs on the lessee when the lease is terminated and should be considered explicitly when making the leasing decision.

The moral of the story for lessees is to read the fine print and request changes to objectionable terms before signing the lease. Here are some ways to reduce the likelihood of unanticipated costs: (1) Specify residual value as a percentage of the initial cost of the equipment. (2) Allow for portions of the equipment to be returned and portions to be purchased at the end of the lease. (3) Specify that disagreements will be settled by arbitration.

Source: Linda Corman, "(Don't) Look Deep into My Lease," *CFO*, July 2006, pp. 71–75.

However, leasing can be a way to circumvent existing loan covenants. If restrictive covenants prohibit a firm from issuing more debt but fail to restrict lease payments, then the firm could effectively increase its leverage by leasing additional assets. Also, firms that are in poor financial condition and face possible bankruptcy may be able to obtain lease financing at a lower cost than comparable debt financing because: (1) Lessors often have a more favorable position than lenders should the lessee actually go bankrupt. (2) Lessors that specialize in certain types of equipment may be in a better position to dispose of repossessed equipment than banks or other lenders.

19-6c Real Estate Leases

Most of our examples have focused on equipment leasing. However, leasing originated with real estate, and such leases still constitute a huge segment of total lease financing. (We distinguish between housing rentals and long-term business leases; our concern is with business leases.) Retailers lease many of their stores. In some situations, retailers have no choice but to lease—this is true of locations in malls and certain office buildings. In other situations, they have a choice of building and owning versus leasing. Law firms and accounting firms, for example, can choose to buy their own facilities or to lease them on a long-term basis (up to 20 or more years).

The type of lease-versus-purchase analysis we discussed in this chapter is just as applicable for real estate as for equipment—conceptually, there is no difference. Of course, such things as maintenance, who the other tenants will be, what alterations can be made, who will pay for alterations, and the like become especially important with real property, but the analytical procedures upon which the lease-versus-buy decision is based are no different from any other lease analysis.

19-6d Vehicle Leases

Vehicle leasing is very popular today both for large corporations and for individuals, especially professionals such as MBAs, doctors, lawyers, and accountants. For corporations, the key factor involved with transportation is often maintenance and disposal of used vehicles—the leasing companies are specialists here, and many businesses prefer to "outsource" services related to autos and trucks. For individuals, leasing is often more convenient, and it may be easier to justify tax deductions on leased than on owned vehicles. Also, most auto leasing to individuals is through dealers. These dealers (and manufacturers) use leasing as a sales tool, and they often make the terms quite attractive—especially when it comes to the down payment, which may be nonexistent in the case of a lease.

Vehicle leasing also permits many individuals to drive more expensive cars than they could otherwise afford. For example, the monthly payment on a new BMW might be $1,500 when financed with a 3-year loan, but the same car, if leased for 3 years, might cost only $749 a month. At first glance, it appears that leasing is less expensive than owning because the monthly payment is so much lower. However, such a simplistic analysis ignores the fact that payments end after the loan is paid off but continue indefinitely under leasing. By using the techniques described in this chapter, individuals can assess the true costs associated with auto leases and then rationally judge the merits of each type of auto financing.

19-6e Leasing and Tax Laws[14]

The ability to structure leases that are advantageous to both lessor and lessee depends in large part on tax laws. The four major tax factors that influence leasing are: (1) investment tax credits, (2) depreciation rules, (3) tax rates, and (4) the alternative minimum tax. In this section, we briefly discuss each of these factors and how they influence leasing decisions.

The investment tax credit (ITC), when it is allowed, is a direct reduction of taxes that occurs when a firm purchases new capital equipment. Prior to 1987, firms could immediately deduct up to 10% of the cost of new capital investments from their corporate tax bills. Thus, a company that bought a $1,000,000 mainframe computer system would get a $100,000 reduction in current-year taxes. Because the ITC goes to the owner of the capital asset, low-tax-bracket companies that could not otherwise use the ITC could use leasing as a vehicle to pass immediate tax savings to high-tax-bracket lessors. The ITC is not currently in effect, but it could be reinstated in the future. If the ITC is put back into law, leasing will become especially attractive to low-tax-bracket firms.

To stimulate the economy in the wake of the global financial crisis of 2007, Congress authorized bonus depreciation rates. For example, in 2011, companies could claim a depreciation expense equal to 100% of the property's basis. Because of the time value of money, the faster an asset can be depreciated, the greater the tax advantages of ownership. However, many companies have lost money in recent years, so they are unable to fully utilize the bonus depreciation, which would reduce the stimulating impact of bonus deprecation. This is where leasing comes into play. Lessors in higher tax brackets can take advantage of the bonus depreciation and pass some of the savings on to low-tax-bracket lessees in the form of lower lease payments. The bonus depreciation provision expired at the beginning of 2014, but in July 2014 the House voted to reinstate it and make it permanent. As of fall 2014, the Senate has not acted on the legislation and so for now bonus depreciation is not in effect.

[14]See chapters 3 and 6 of Schallheim's *Lease or Buy?* (cited in footnote 1) for an in-depth discussion of tax effects on leasing.

Lease Securitization

Compared with many markets, the leasing market is fragmented and inefficient. There are millions of potential lessees, including all equipment users. Some are in high tax brackets, some are in low brackets. Some are financially sophisticated, some are not. Some have excellent credit ratings, some have poor credit. On the other side of the market are millions of potential lessors—including equipment manufacturers, banks, and individual investors—with different tax brackets and risk tolerances. If each lessee had to negotiate a separate deal for each lease, then information and search costs would be so high that few leases would be written.

Tax laws complicate the picture. For example, the alternative minimum tax (AMT) often has the effect of limiting the amount of depreciation a firm can utilize. In addition, a firm can't take a full half-year's depreciation on purchases in the fourth quarter if those purchases amount to more than 40% of total annual purchases. In this case the firm can take only a half-quarter's depreciation, which is the equivalent of one-eighth of a year's depreciation.

Lease brokers often served as facilitators in this complicated and inefficient market. Working with many different equipment manufacturers and lenders, brokers are in a position to match lessees with appropriate lessors in such a way that the full benefit of tax laws can be utilized.

Lease securitization, a new procedure, is the ultimate method of matching lessees with appropriate lessors. The first step is to create a portfolio consisting of numerous leases. The second step is to divide the leasing cash flows into different streams of income, called *tranches.* For example, one tranche might contain only lease payments, which would appeal to an investor in a low tax bracket. A second tranche might consist of depreciation, which a high-tax-bracket investor could use to shelter income from other sources. A third might contain the residual cash flows, which will occur in the future when the leases end. This tranche would appeal to a high-tax-bracket investor who can take some risk. Tranches can also be allocated according to the credit rating of the lessees, allowing investors with different risk tolerances to take on their desired level of risk.

In addition, a company might obtain a lease in its fourth quarter, but if this is the third quarter of the *lessor's* fiscal year, the lessor can take a full half-year's depreciation.

Sound complicated? It is, but it's an efficient answer to an inefficient market.

Source: SMG Fairfax, Knoxville, Tennessee.

Finally, the alternative minimum tax (AMT) also affects leasing activity. Corporations are permitted to use accelerated depreciation and other tax shelters on their tax books but then use straight-line depreciation for reporting results to shareholders. Thus, some firms report to the IRS that they are doing poorly, and hence pay little or no taxes, but report high earnings to shareholders. The corporate AMT, which is roughly computed by applying a 20% tax rate to the profits reported to shareholders, is designed to force highly profitable companies to pay at least some taxes even if they have tax shelters that push their taxable income to zero. In effect, all firms (and individuals) must compute the "regular" tax and the AMT tax, and then pay the higher of the two.

Companies with large AMT liabilities look for ways to reduce their tax bills by lowering reported income. Leasing can be beneficial here—a relatively short-term lease with high annual payments will increase reported expenses and thus lower reported profits. Note that the lease does not have to qualify as a guideline lease and be deducted for regular tax purposes—all that is needed is to lower reported income as shown on the income statement.

We see that tax laws and differential tax rates between lessors and lessees can be a motivating force for leasing. However, as we discuss in the next section, there are some sound nontax economic reasons why firms lease plants and equipment.

SELF-TEST

Does leasing lead to increased credit availability?

How do tax laws affect leasing?

19-7 Other Reasons for Leasing

Up to this point, we have noted that the tax rate or other differentials are generally necessary to make leasing attractive to both the lessee and the lessor. If the lessee and the lessor are facing different tax situations, including the alternative minimum tax, then it is often possible to structure a lease that is beneficial to both parties. However, there are other reasons that firms might want to lease an asset rather than buy it.

More than half of all commercial aircraft are leased, and smaller airlines, especially in developing nations, lease an especially high percentage of their planes. One of the reasons for this is that airlines can reduce their risks by leasing. If an airline purchased all its aircraft, it would be hampered in its ability to respond to changing market conditions. Because they have become specialists at matching airlines with available aircraft, the aircraft lessors (which are multibillion-dollar concerns) are quite good at managing the changing demand for different types of aircraft. This permits them to offer attractive lease terms. In this situation, *leasing provides operating flexibility*. Leasing is not necessarily less expensive than buying, but the operating flexibility is quite valuable.

Leasing is also an attractive alternative for many high-technology items that are subject to rapid and unpredictable technological obsolescence. Suppose a small rural hospital wants to buy a magnetic resonance imaging (MRI) device. If it buys the MRI equipment, then it is exposed to the risk of technological obsolescence. In a short time, some new technology might lower the value of the current system and thus render the project unprofitable. Because it does not use much equipment of this nature, the hospital would bear a great deal of risk if it bought the MRI device. However, a lessor that specializes in state-of-the-art medical equipment would be exposed to significantly less risk. By purchasing and then leasing many different items, the lessor benefits from diversification. Of course, over time some items will probably lose more value than the lessor expected, but this will be offset by other items that retain more value than expected. Also, because such a leasing company will be especially familiar with the market for used medical equipment, it can refurbish the equipment and then get a better price in the resale market than could a remote rural hospital. For these reasons, *leasing can reduce the risk of technological obsolescence.*

Leasing can also be attractive when a firm is uncertain about the demand for its products or services and thus about how long the equipment will be needed. Again, consider the hospital industry. Hospitals often offer services that are dependent on a single staff member—for example, a physician who performs liver transplants. To support the physician's practice, the hospital might have to invest millions in equipment that can be used only for this particular procedure. The hospital will charge for the use of the equipment, and if things go as expected, the investment will be profitable. However, if the physician leaves the hospital and if no replacement can be recruited, then the project is dead and the equipment becomes useless to the hospital. In this case, a lease with a cancelation clause would permit the hospital to simply return the equipment. The lessor would charge something for the cancelation clause, and this would lower the expected profitability of the project, but it would provide the hospital with an option to abandon the equipment, and the value of the option could easily exceed the incremental cost of the cancelation clause. The leasing company would be willing to write this option because it is in a better position to remarket the equipment, either by writing another lease or by selling it outright.

The leasing industry recently introduced a type of lease that even transfers some of a project's operating risk from the lessee to the lessor and also motivates the lessor to maintain the leased equipment in good working order. Instead of making a fixed rental payment, the lessee pays a fee each time the leased equipment is used. This type of lease

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. originated with copy machines, where the lessee pays so much per month plus an additional amount per copy made. If the machine breaks down, no copies are made and the lessor's rental income declines. This motivates the lessor to repair the machine quickly.

This type of lease is also used in the health care industry, where it is called a "per-procedure lease." For example, a hospital might lease an X-ray machine for a fixed fee per X-ray, say, $5. If demand for the machine's X-rays is less than expected by the hospital, then revenues will be lower than expected—but so will the machine's capital costs. Conversely, high demand would lead to higher than expected lease costs—but these would be offset by higher than expected revenues. By using a per-procedure lease, the hospital is converting a fixed cost for the equipment into a variable cost and thereby reducing the machine's operating leverage and break-even point. The net effect is to reduce the project's risk. Of course, the expected cost of a per-procedure lease might be more than the cost of a conventional lease, but the risk reduction benefit could be worth the cost. Note too that if the lessor writes a large number of per-procedure leases then much of the riskiness inherent in such leases can be eliminated by diversification, so the risk premiums that lessors build into per-procedure lease payments could be low enough to attract potential lessees.

Some companies also find leasing attractive because the lessor is able to provide servicing on favorable terms. For example, Virco Manufacturing, a company that makes school desks and other furniture, recently leased 25 truck tractors and 140 trailers that it uses to ship furniture from its plant. The lease agreement, with a large leasing company that specializes in purchasing, maintaining, and then reselling trucks, permitted the replacement of an aging fleet that Virco had built up over the years. "We are pretty good at manufacturing furniture, but we aren't very good at maintaining a truck fleet," said Virco's CFO.

There are other reasons that might cause a firm to lease an asset rather than buy it. Often these reasons are difficult to quantify and so cannot be easily incorporated into an NPV or IRR analysis. Nevertheless, a sound lease decision must begin with a quantitative analysis, and then qualitative factors can be considered before making the final lease-or-buy decision.[15]

SELF-TEST

Describe some economic factors that might provide an advantage to leasing.

SUMMARY

In the United States, more than 30% of all equipment is leased, as is a great deal of real estate. Consequently, leasing is an important financing vehicle. In this chapter, we discussed the leasing decision from the standpoints of both the lessee and the lessor. The key concepts covered are listed below.

- The five most important types of lease agreement are: (1) the **operating lease**; (2) the **financial lease**, which is also called a **capital lease**; (3) the **sale-and-leaseback**; (4) the **combination lease**; and (5) the **synthetic lease**.

[15]For more on leasing, see Thomas J. Finucane, "Some Empirical Evidence on the Use of Financial Leases," *The Journal of Financial Research*, Fall 1988, pp. 321–333; and Lawrence D. Schall, "The Evaluation of Lease Financing Opportunities," *Midland Corporate Finance Journal*, Spring 1985, pp. 48–65.

- The IRS has specific guidelines that apply to lease arrangements. A lease that meets these guidelines is called a **guideline lease**, or a **tax-oriented lease**, because the IRS permits the lessor to deduct the asset's depreciation and allows the lessee to deduct the lease payments. A lease that does not meet the IRS guidelines is called a **non-tax-oriented lease**, in which case ownership for tax purposes resides with the lessee rather than the lessor.
- **FASB Statement 13** spells out the conditions under which a lease must be **capitalized** (shown directly on the balance sheet) as opposed to shown only in the notes to the financial statements. Generally, leases that run for a period equal to or greater than 75% of the asset's life must be capitalized.
- The lessee's analysis consists basically of a comparison of the PV of leasing versus the PV of owning. The difference in these PV's is called the **net advantage to leasing (NAL)**.
- One of the key issues in the lessee's analysis is the appropriate discount rate. A lease is a substitute for debt, cash flows in a lease analysis are stated on an after-tax basis, and cash flows are known with relative certainty, so the appropriate discount rate is the lessee's after-tax cost of debt. A higher discount rate may be used on the **residual value** if it is substantially riskier than the other flows.
- The lessor evaluates the lease as an **investment**. If the lease's NPV is greater than zero or if its IRR is greater than the lessor's opportunity cost, then the lease should be written.
- Leasing is motivated by various differences between lessees and lessors. Three of the most important reasons for leasing are: (1) tax rate differentials, (2) leases in which the lessor is better able than the lessee to bear the residual value risk, and (3) situations in which the lessor can maintain the leased equipment more efficiently than the lessee can.
- ***Web Extension 19A*** explains leasing feedback effects, ***Web Extension 19B*** explains the percentage cost of leasing, and ***Web Extension 19C*** explains leveraged leases.

QUESTIONS

(19-1) Define each of the following terms:

a. Lessee; lessor
b. Operating lease; financial lease; sale-and-leaseback; combination lease; synthetic lease; SPE
c. Off–balance sheet financing; capitalizing
d. FASB Statement 13
e. Guideline lease
f. Residual value
g. Lessee's analysis; lessor's analysis
h. Net advantage to leasing (NAL)
i. Alternative minimum tax (AMT)

(19-2) Distinguish between operating leases and financial leases. Would you be more likely to find an operating lease employed for a fleet of trucks or for a manufacturing plant?

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(19-3) Are lessees more likely to be in higher or lower income tax brackets than lessors?

(19-4) Commercial banks moved heavily into equipment leasing during the early 1970s, acting as lessors. One major reason for this invasion of the leasing industry was to gain the benefits of accelerated depreciation and the investment tax credit on leased equipment. During this same period, commercial banks were investing heavily in municipal securities, and they were also making loans to real estate investment trusts (REITs). In the mid-1970s, these REITs got into such serious difficulty that many banks suffered large losses on their REIT loans. Explain how its investments in municipal bonds and REITs could reduce a bank's willingness to act as a lessor.

(19-5) One advantage of leasing voiced in the past is that it kept liabilities off the balance sheet, thus making it possible for a firm to obtain more leverage than it otherwise could have. This raised the question of whether or not both the lease obligation and the asset involved should be capitalized and shown on the balance sheet. Discuss the pros and cons of capitalizing leases and related assets.

(19-6) Suppose there were no IRS restrictions on what constituted a valid lease. Explain, in a manner a legislator might understand, why some restrictions should be imposed. Illustrate your answer with numbers.

(19-7) Suppose Congress enacted new tax law changes that would: (1) permit equipment to be depreciated over a shorter period, (2) lower corporate tax rates, and (3) reinstate the investment tax credit. Discuss how each of these potential changes would affect the relative volume of leasing versus conventional debt in the U.S. economy.

(19-8) In our Anderson Company example, we assumed that the lease could not be canceled. What effect would a cancelation clause have on the lessee's analysis? On the lessor's analysis?

SELF-TEST PROBLEM

Solution Shown in Appendix A

(ST-1)
Lease versus Buy

The Randolph Teweles Company (RTC) has decided to acquire a new truck. One alternative is to lease the truck on a 4-year guideline contract for a lease payment of $10,000 per year, with payments to be made at the *beginning* of each year. The lease would include maintenance. Alternatively, RTC could purchase the truck outright for $40,000, financing the purchase by a bank loan for the net purchase price and amortizing the loan over a 4-year period at an interest rate of 10% per year. Under the borrow-to-purchase arrangement, RTC would have to maintain the truck at a cost of $1,000 per year, payable at year end. The truck falls into the MACRS 3-year class. It has a residual value of $10,000, which is the expected market value after 4 years, when RTC plans to replace the truck irrespective of whether it leases or buys. RTC has a marginal federal-plus-state tax rate of 40%.

a. What is RTC's present value of leasing?
b. What is RTC's present value of owning? Should the truck be leased or purchased?

PROBLEMS

Answers Are in Appendix B

EASY PROBLEMS 1–2

(19-1) Balance Sheet Effects

Reynolds Construction (RC) needs a piece of equipment that costs $200. RC can either lease the equipment or borrow $200 from a local bank and buy the equipment. If the equipment is leased, the lease would *not* have to be capitalized. RC's balance sheet prior to the acquisition of the equipment is as follows:

Current assets	$300	Debt	$400
Net fixed assets	500	Equity	400
Total assets	$800	Total claims	$800

a. (1) What is RC's current debt ratio?
   (2) What would be the company's debt ratio if it purchased the equipment?
   (3) What would be the debt ratio if the equipment were leased?
b. Would the company's financial risk be different under the leasing and purchasing alternatives?

(19-2) Lease versus Buy

Consider the data in Problem 19-1. Assume that RC's tax rate is 40% and that the equipment's depreciation would be $100 per year. If the company leased the asset on a 2-year lease, the payment would be $110 at the beginning of each year. If RC borrowed and bought, the bank would charge 10% interest on the loan. In either case, the equipment is worth nothing after 2 years and will be discarded. Should RC lease or buy the equipment?

INTERMEDIATE PROBLEMS 3–4

(19-3) Balance Sheet Effects

Two companies, Energen and Hastings Corporation, began operations with identical balance sheets. A year later, both required additional fixed assets at a cost of $50,000. Energen obtained a 5-year, $50,000 loan at an 8% interest rate from its bank. Hastings, on the other hand, decided to lease the required $50,000 capacity for 5 years, and an 8% return was built into the lease. The balance sheet for each company, before the asset increases, follows:

Current assets	$ 25,000	Debt	$ 50,000
Fixed assets	125,000	Equity	100,000
Total assets	$150,000	Total claims	$150,000

a. Show the balance sheets for both firms after the asset increases, and calculate each firm's new debt ratio. (Assume that the lease is not capitalized.)
b. Show how Hastings's balance sheet would look immediately after the financing if it capitalized the lease.

(19-4) Lease versus Buy

Big Sky Mining Company must install $1.5 million of new machinery in its Nevada mine. It can obtain a bank loan for 100% of the purchase price, or it can lease the machinery. Assume that the following facts apply.

1. The machinery falls into the MACRS 3-year class.
2. Under either the lease or the purchase, Big Sky must pay for insurance, property taxes, and maintenance.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

3. The firm's tax rate is 40%.
4. The loan would have an interest rate of 15%. It would be nonamortizing, with only interest paid at the end of each year for four years and the principal repaid at Year 4.
5. The lease terms call for $400,000 payments at the end of each of the next 4 years.
6. Big Sky Mining has no use for the machine beyond the expiration of the lease, and the machine has an estimated residual value of $250,000 at the end of the 4th year.

What is the NAL of the lease?

CHALLENGING PROBLEM 5

(19-5) Lease versus Buy

Sadik Industries must install $1 million of new machinery in its Texas plant. It can obtain a 6-year bank loan for 100% of the cost at a 14% interest rate with equal payments at the end of each year. Sadik's tax rate is 34%. The equipment falls in the MACRS 3-year class.

Alternatively, a Texas investment banking firm that represents a group of investors can arrange a guideline lease calling for payments of $320,000 at the end of each year for 3 years. Under the proposed lease terms, the Sadik must pay for insurance, property taxes, and maintenance.

Sadik must use the equipment if it is to continue in business, so it will almost certainly want to acquire the property at the end of the lease. If it does, then under the lease terms it can purchase the machinery at its fair market value at Year 3. The best estimate of this market value is $200,000, but it could be much higher or lower under certain circumstances. If purchased at Year 3, the used equipment would fall into the MACRS 3-year class. Sadik would actually be able to make the purchase on the last day of the year (i.e., slightly before Year 3), so Sadik would get to take the first depreciation expense at Year 3 (the remaining depreciation expenses would be from Year 4 through Year 6). On the time line, Sadik would show the cost of purchasing the used equipment at Year 3 *and* its depreciation expenses starting at Year 3.

To assist management in making the proper lease-versus-buy decision, you are asked to answer the following questions:

a. What is the net advantage of leasing? Should Sadik take the lease?
b. Consider the $200,000 estimated residual value. How high could the residual value get before the net advantage of leasing falls to zero?

SPREADSHEET PROBLEM

(19-6) Build a Model: Lessee's Analysis

Start with the partial model in the file ***Ch19 P06 Build a Model.xlsx*** on the textbook's Web site. As part of its overall plant modernization and cost reduction program, Western Fabrics' management has decided to install a new automated weaving loom. In the capital budgeting analysis of this equipment, the IRR of the project was found to be 20% versus the project's required return of 12%.

resource

The loom has an invoice price of $250,000, including delivery and installation charges. The funds needed could be borrowed from the bank through a 4-year amortized loan at a 10% interest rate, with payments to be made at the end of each year. In the event the loom is purchased, the manufacturer will contract to maintain and service it for a fee of $20,000 per year paid at the end of each year. The loom falls in the MACRS 5-year class, and Western's marginal federal-plus-state tax rate is 40%.

Aubey Automation Inc., maker of the loom, has offered to lease the loom to Western for $70,000 upon delivery and installation (at $t = 0$) plus four additional annual lease

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

payments of $70,000 to be made at the end of Years 1 to 4. (Note that there are five lease payments in total.) The lease agreement includes maintenance and servicing. The loom has an expected life of 8 years, at which time its expected salvage value is zero; however, after 4 years its market value is expected to equal its book value of $42,500. Western plans to build an entirely new plant in 4 years, so it has no interest in either leasing or owning the proposed loom for more than that period.

a. Should the loom be leased or purchased?
b. The salvage value is clearly the most uncertain cash flow in the analysis. What effect would a salvage value risk adjustment have on the analysis? (Assume that the appropriate salvage value pre-tax discount rate is 15%.)
c. Assuming that the after-tax cost of debt should be used to discount all anticipated cash flows, at what lease payment would the firm be indifferent to either leasing or buying?

MINI CASE

Lewis Securities Inc. has decided to acquire a new market data and quotation system for its Richmond home office. The system receives current market prices and other information from several online data services and then either displays the information on a screen or stores it for later retrieval by the firm's brokers. The system also permits customers to call up current quotes on terminals in the lobby.

The equipment costs $1,000,000 and, if it were purchased, Lewis could obtain a term loan for the full purchase price at a 10% interest rate. Although the equipment has a 6-year useful life, it is classified as a special-purpose computer and therefore falls into the MACRS 3-year class. If the system were purchased, a 4-year maintenance contract could be obtained at a cost of $20,000 per year, payable at the beginning of each year. The equipment would be sold after 4 years, and the best estimate of its residual value is $200,000. However, because real-time display system technology is changing rapidly, the actual residual value is uncertain.

As an alternative to the borrow-and-buy plan, the equipment manufacturer informed Lewis that Consolidated Leasing would be willing to write a 4-year guideline lease on the equipment, including maintenance, for payments of $260,000 at the beginning of each year. Lewis's marginal federal-plus-state tax rate is 40%. You have been asked to analyze the lease-versus-purchase decision and, in the process, to answer the following questions:

a. (1) Who are the two parties to a lease transaction?
   (2) What are the five primary types of leases, and what are their characteristics?
   (3) How are leases classified for tax purposes?
   (4) What effect does leasing have on a firm's balance sheet?
   (5) What effect does leasing have on a firm's capital structure?
b. (1) What is the present value of owning the equipment? (*Hint:* Set up a time line that shows the net cash flows over the period $t = 0$ to $t = 4$, and then find the PV of these net cash flows, or the PV cost of owning.)
   (2) Explain the rationale for the discount rate you used to find the PV.
c. What is Lewis's present value of leasing the equipment? (*Hint:* Again, construct a time line.)
d. What is the net advantage to leasing (NAL)? Does your analysis indicate that Lewis should buy or lease the equipment? Explain.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

e. Now assume that the equipment's residual value could be as low as $0 or as high as $400,000, but $200,000 is the expected value. Because the residual value is riskier than the other relevant cash flows, this differential risk should be incorporated into the analysis. Describe how this could be accomplished. (No calculations are necessary, but explain how you would modify the analysis if calculations were required.) What effect would the residual value's increased uncertainty have on Lewis' lease-versus-purchase decision?

f. The lessee compares the present value of owning the equipment with the present value of leasing it. Now put yourself in the lessor's shoes. In a few sentences, how should you analyze the decision to write or not to write the lease?

g. (1) Assume that the lease payments were actually $280,000 per year, that Consolidated Leasing is also in the 40% tax bracket, and that it also forecasts a $200,000 residual value. Also, to furnish the maintenance support, Consolidated would have to purchase a maintenance contract from the manufacturer at the same $20,000 annual cost, again paid in advance. Consolidated Leasing can obtain an expected 10% pre-tax return on investments of similar risk. What would be Consolidated's NPV and IRR of leasing under these conditions?

(2) What do you think the lessor's NPV would be if the lease payment were set at $260,000 per year? (*Hint:* The lessor's cash flows would be a "mirror image" of the lessee's cash flows.)

h. Lewis's management has been considering moving to a new downtown location, and they are concerned that these plans may come to fruition prior to the equipment lease's expiration. If the move occurs, then Lewis would buy or lease an entirely new set of equipment, so management would like to include a cancelation clause in the lease contract. What effect would such a clause have on the riskiness of the lease from Lewis's standpoint? From the lessor's standpoint? If you were the lessor, would you insist on changing any of the other lease terms if a cancelation clause were added? Should the cancelation clause contain provisions similar to call premiums or any restrictive covenants and/or penalties of the type contained in bond indentures? Explain your answer.

SELECTED ADDITIONAL CASES

The following cases from CengageCompose cover many of the concepts discussed in this chapter and are available at **http://compose.cengage.com.**

Klein-Brigham Series:
Case 25, "Environmental Sciences, Inc.," Case 49, "Agro Chemical Corporation," Case 69, "Friendly Food Stores, Inc.," and Case 26, "Prudent Solutions, Inc.," all examine the lease decision from the perspectives of both the lessee and the lessor.

Brigham-Buzzard Series:
Case 12, "Powerline Network Corporation (Leasing)."

CHAPTER 20

Hybrid Financing: Preferred Stock, Warrants, and Convertibles

What do Tesla, Twitter, and Fiat Chrysler have in common? Two are auto manufacturers, Tesla and Fiat Chrysler, although their product lines are a bit different. Two are high-tech companies, Tesla and Twitter, but they are in very different industries. Perhaps the biggest common characteristic is that each issued convertible bonds in 2014—Twitter raised $1.8 billion, Tesla raised $2 billion, and Fiat Chrysler raised $2.5 billion. In fact, more convertible bonds were issued in 2014 than in any year since 2008.

What is driving this upsurge in convertible debt? A convertible bond has fixed coupon payments and a final face value payment at maturity. But, as its name implies, the owner of a convertible bond can convert the bond into shares of stock. When compared with owning stock, investors like the protection provided by convertible bonds—even if the stock price falls, the investor will still receive coupon payments and the face value at maturity.

However, investors have to accept a lower coupon rate than on nonconvertible debt to get this protection, which is why some companies like convertible debt. For example, Twitter's debt has a 1% coupon and Tesla's pays 1.25%.

Unlike the Tesla and Twitter bonds, whose investor can choose not to convert if the stock prices fall, the Fiat Chrysler bondholders are *required* to convert their bonds into shares of stock. However, it won't be Fiat Chrysler stock! Instead, it will be stock in a newly created Ferrari corporation when Fiat Chrysler spins off its Ferrari operations.

Think about these companies as you read the chapter.

resource

The textbook's Web site contains an Excel *file that will guide you through the chapter's calculations. The file for this chapter is* ***Ch20 Tool Kit.xlsx****, and we encourage you to open the file and follow along as you read the chapter.*

In previous chapters, we examined common stocks and various types of long-term debt. In this chapter, we examine three other securities used to raise long-term capital: (1) *preferred stock*, which is a hybrid security that represents a cross between debt and common equity, (2) *warrants*, which are derivative securities issued by firms to facilitate the issuance of some other type of security, and (3) *convertibles*, which combine the features of debt (or preferred stock) and warrants.

20-1 Preferred Stock

Preferred stock is a hybrid—it is similar to bonds in some respects and to common stock in other ways. Accountants classify preferred stock as equity; hence they show it on the balance sheet as an equity account. However, from a financial perspective preferred stock lies somewhere between debt and common equity: It imposes a fixed charge and thus increases the firm's financial leverage, yet omitting the preferred dividend does not force a company into bankruptcy. Also, unlike interest on debt, preferred dividends are not deductible by the issuing corporation, so preferred stock has a higher cost of capital than debt. We first describe the basic features of preferred stock, after which we discuss the types of preferred stock and the advantages and disadvantages of preferred stock.

20-1a Basic Features

Preferred stock has a par (or liquidating) value, often either \$25 or \$100. The dividend is stated as either a percentage of par, as so many dollars per share, or both ways. For example, several years ago Klondike Paper Company sold 150,000 shares of \$100 par value perpetual preferred stock for a total of \$15 million. This preferred stock had a stated annual dividend of \$12 per share, so the preferred dividend yield was \$12/\$100 = 0.12, or 12%, at the time of issue. The dividend was set when the stock was issued; it will not be changed in the future. Therefore, if the required rate of return on preferred, r_{ps}, changes from 12% after the issue date—as it did—then the market price of the preferred stock will go up or down. Currently, r_{ps} for Klondike Paper's preferred is 9%, and the price of the preferred has risen from \$100 to \$12/0.09 = \$133.33.

If the preferred dividend is not earned, the company does not have to pay it. However, most preferred issues are **cumulative**, meaning that the cumulative total of unpaid preferred dividends must be paid before dividends can be paid on the common stock. Unpaid preferred dividends are called **arrearages**. Dividends in arrears do not earn interest; thus, arrearages do not grow in a compound interest sense, they only grow from additional nonpayments of the preferred dividend. Also, many preferred stocks accrue arrearages for only a limited number of years—so that, for example, the cumulative feature may cease after 3 years. However, the dividends in arrears continue in force until they are paid.

Preferred stock normally has no voting rights. However, most preferred issues stipulate that the preferred stockholders can elect a minority of the directors—say, three out of ten—if the preferred dividend is passed (omitted). Some preferreds even entitle their holders to elect a majority of the board.

Although nonpayment of preferred dividends will not trigger bankruptcy, corporations issue preferred stock with every intention of paying the dividend. Even if passing the dividend does not give the preferred stockholders control of the company, failure to pay a preferred dividend precludes payment of common dividends. In addition, passing the dividend makes it difficult to raise capital by selling bonds and virtually impossible to sell more preferred or common stock except at rock-bottom prices. However, having preferred stock outstanding does give a firm the chance to overcome its difficulties: If bonds had been used instead of preferred stock, a company could be forced into bankruptcy

before it could straighten out its problems. Thus, *from the viewpoint of the issuing corporation, preferred stock is less risky than bonds.*

WWW

For updates, go to **http://finance.yahoo.com** *and get quotes for AA-P, Alcoa's 3.75% preferred stock. For an updated bond yield, go to FINRA's site at* **http://finra-markets.morningstar.com/BondCenter/Default.jsp** *and search for Alcoa bonds.*

For an investor, however, preferred stock is riskier than bonds: (1) Preferred stockholders' claims are subordinated to those of bondholders in the event of liquidation. (2) Bondholders are more likely to continue receiving income during hard times than are preferred stockholders. Accordingly, investors require a higher after-tax rate of return on a given firm's preferred stock than on its bonds. However, because 70% of preferred dividends is exempt from corporate taxes, preferred stock is attractive to corporate investors. Indeed, high-grade preferred stock, on average, sells on a lower pre-tax yield basis than high-grade bonds. As an example, Alcoa has preferred stock with an annual dividend of $3.75 (a 3.75% rate applied to $100 par value). In May 2014, Alcoa's preferred stock had a price of $86.50, for a market yield of about $3.75/$84.50 = 4.44%. Alcoa's long-term bonds that mature in 2037 provided a yield of 6.0%, which is 1.56 percentage points *more* than its preferred, even though preferred stock is riskier than debt. The tax treatment accounted for this differential; the *after-tax yield* to corporate investors was greater on the preferred stock than on the bonds because 70% of the dividend may be excluded from taxation by a corporate investor.[1]

About half of all preferred stock issued in recent years has been convertible into common stock. We discuss convertibles in Section 20-3.

Some preferred stocks are similar to perpetual bonds in that they have no maturity date, but most new issues now have specified maturities. For example, many preferred shares have a sinking fund provision that calls for the retirement of 2% of the issue each year, meaning the issue will "mature" in a maximum of 50 years. Also, many preferred issues are callable by the issuing corporation, which can also limit the life of the preferred.[2]

Nonconvertible preferred stock is virtually all owned by corporations, which can take advantage of the 70% dividend exclusion to obtain a higher after-tax yield on preferred stock than on bonds. Individuals should not own preferred stocks (except convertible preferreds)—they can get higher yields on safer bonds, so it is not logical for them to hold preferreds.[3] As a result of this ownership pattern, the volume of preferred stock financing is geared to the supply of money in the hands of corporate investors. When the supply of such money is plentiful, the prices of preferred stocks are bid up, their yields fall, and investment bankers suggest that companies in need of financing consider issuing preferred stock.

[1]For example, the after-tax yield on an 8.1% bond to a corporate investor in the 34% marginal tax rate bracket is 8.1%(1−T) = 5.3%. The after-tax yield on a 7.0% preferred stock is 7.0%(1−Effective T) = 7.0%[1 − (0.30)(0.34)] = 6.3%. Also, note that tax law prevents arbitrage. If a firm issues debt and uses the proceeds to purchase another firm's preferred stock, then the 70% dividend exclusion is voided.

[2]Prior to the late 1970s, virtually all preferred stock was perpetual and almost no issues had sinking funds or call provisions. Then insurance company regulators, worried about the unrealized losses the companies had been incurring on preferred holdings as a result of rising interest rates, made changes essentially mandating that insurance companies buy only limited life preferreds. From that time on, virtually no new preferred has been perpetual. This example illustrates the way securities change as a result of changes in the economic environment.

[3]Since 2003, qualified dividends received by individuals are taxed at a capital gains rate rather than as ordinary income. This makes preferred stock more attractive relative to bonds, putting individual investors in much the same boat as corporations. For example, a corporation in the 35% tax bracket with a 70% dividend exclusion faces a (0.35)(1 − 0.70) = 10.5% tax rate on dividend income as compared to a 35% rate on interest income. Most individuals face a dividend tax rate of 15%, and high income earners would face a 35% tax on ordinary income. Thus there is a tax advantage for dividend income for both individuals and corporations, although the advantage is larger for corporations.Also, some financially engineered preferred stock has "dividends" that the paying company can deduct for tax purposes in the same way that interest payments are deductible. Therefore, the company is able to pay a higher rate on such preferred stock, making it potentially attractive to individual investors. These securities trade under a variety of colorful names, including MIPS (Modified Income Preferred Securities), QUIPS (Quarterly Income Preferred Securities), TOPrS (Trust Originated Preferred Stock), and QUIDS (Quarterly Income Debt Securities). However, dividends from these hybrid securities are not subject to the 70% corporate exclusion and are taxed as ordinary income for individual investors.

The Romance Had No Chemistry, but It Had a Lot of Preferred Stock!

On April 1, 2009, Dow Chemical Company merged with Rohm & Haas after a bitter dispute over the interpretation of their previous merger agreement. So even though the two companies make chemicals, there apparently wasn't much chemistry by the time the merger was completed.

To raise cash for the $78.97 per share purchase of Rohm & Haas' outstanding shares, Dow borrowed over $9 billion from Citibank and also issued $4 billion in convertible preferred stock to Berkshire Hathaway and The Kuwait Investment Authority.

The Haas Family Trusts and Paulson & Company were large shareholders in Rohm & Haas. As part of the deal, they sold their shares to Dow with one hand and bought $3 billion in preferred stock from Dow with the other. This preferred stock pays a cash dividend of 7%. It also pays an 8% "dividend" that either can be cash or additional shares of the preferred stock, with the choice left to Dow; this is called a payment-in-kind (PIK) dividend.

These terms mean that Dow can conserve cash if it runs into difficult times: Dow can pay the 8% in additional stock and Dow can even defer payment of the 7% cash dividend without risk of bankruptcy. But if this happens, a troubled marriage is likely to cause even more grief.

Source: 8-K reports from the SEC filed on March 12, 2009, and April 1, 2009.

For issuers, preferred stock has a tax *disadvantage* relative to debt: Interest expense is deductible, but preferred dividends are not. Still, firms with low tax rates may have an incentive to issue preferred stock that can be bought by high-tax-rate corporate investors, who can take advantage of the 70% dividend exclusion. If a firm has a lower tax rate than potential corporate buyers, then the firm might be better off issuing preferred stock than debt. The key here is that the tax advantage to a high-tax-rate corporation is greater than the tax disadvantage to a low-tax-rate issuer. As an illustration, assume that risk differentials between debt and preferred would require an issuer to set the interest rate on new debt at 10% and the dividend yield on new preferred stock 2% higher, or at 12% in a no-tax world. However, when taxes are considered, a corporate buyer with a high tax rate—say, 40%—might be willing to buy the preferred stock if it has an 8% before-tax yield. This would produce an $8\%(1 - \text{Effective T}) = 8\%[1 - 0.30(0.40)] = 7.04\%$ after-tax return on the preferred versus $10\%(1 - 0.40) = 6.0\%$ on the debt. If the issuer has a low tax rate—say, 10%—then its after-tax costs would be $10\%(1 - \text{T}) = 10\%(0.90) = 9\%$ on the bonds and 8% on the preferred. Thus, the security with lower risk to the issuer, preferred stock, also has a lower cost. Such situations can make preferred stock a logical financing choice.[4]

20-1b Other Types of Preferred Stock

In addition to "plain vanilla" preferred stock, there are two other variations: adjustable rate and market auction preferred stock.

ADJUSTABLE RATE PREFERRED STOCK

Instead of paying fixed dividends, **adjustable rate preferred stock (ARP)** has dividends tied to the rate on Treasury securities. ARPs are issued mainly by utilities and large commercial banks. When ARPs were first developed, they were touted as nearly perfect short-term corporate investments because: (1) Only 30% of the dividends are taxable to

[4]For more on preferred stock, see Arthur L. Houston Jr. and Carol Olson Houston, "Financing with Preferred Stock," *Financial Management*, Autumn 1990, pp. 42–54; and Michael J. Alderson and Donald R. Fraser, "Financial Innovations and Excesses Revisited: The Case of Auction Rate Preferred Stock," *Financial Management*, Summer 1993, pp. 61–75.

Hybrids Aren't Only for Corporations

The Cooperative Regions of Organic Producer Pools (CROPP) markets organic produce under such brand names as Organic Valley and Organic Prairie and is a supplier to Stonyfield, maker of organic yogurt. CROPP is not a corporation or a partnership. It is a cooperative, which is an organization that provides services for its owner/members. In this case, CROPP purchases produce from its members, processes the produce, and then resells it. Profits are redistributed to the owner/members as dividends.

With the beginnings of the financial recovery and an overall increase in the demand for organic products, CROPP's sales grew 18% in 2009 to over $600 million. High growth requires investments in operating assets, causing CROPP to need $14 million in additional external financing. CROPP decided to raise the funds by issuing preferred stock to members and non-members. CROPP had successfully issued preferred stock in the past and this issue was a $50 par, 6% cumulative dividend, non-voting preferred stock, and was sold for $50 per share. CROPP chose not to use an investment banker for this issue; the co-op's investor relations manager was in charge of marketing and selling the preferred stock and CROPP saved quite a bit of money in fees with issuance costs totaling about 4.5% rather than the 7% or more charged by an investment bank.

Unlike preferred stock issued by corporations, dividends on preferred stock issued by a Section 521 cooperative such as CROPP can be deducted from its pre-tax income, and the dividend recipient treats it as ordinary income for tax purposes. Therefore this preferred stock is treated like perpetual debt for tax purposes. Why then would CROPP issue preferred stock rather than debt? The simple reason is that preferred stock is non-recourse. If CROPP misses a dividend payment, the dividend accrues, but the preferred stockholder cannot force CROPP into bankruptcy. This flexibility is valuable, especially in an industry as volatile as farming.

corporations. (2) The floating-rate feature was supposed to keep the issue trading at near par. The new security proved to be popular as a short-term investment for firms with idle cash, so mutual funds that held ARPs sprouted like weeds (and shares of these funds, in turn, were purchased by corporations). However, the ARPs still had some price volatility due to: (1) changes in the riskiness of the issuers (some big banks that had issued ARPs, such as Continental Illinois, ran into serious loan default problems) and (2) fluctuations in Treasury yields between dividend rate adjustment dates. Therefore, the ARPs had too much price instability to be held in the liquid asset portfolios of many corporate investors.

MARKET AUCTION PREFERRED STOCK

In 1984, investment bankers introduced **money market preferred stock**, which is also called **market auction preferred stock**.[5] Here the underwriter conducts an auction on the issue every 7 weeks. (To get the 70% exclusion from taxable income, buyers must hold the stock for at least 46 days.) Holders who want to sell their shares can put them up for auction at par value. Buyers then submit bids in the form of the yields they are willing to accept over the next 7-week period. The yield set on the issue for the coming period is the lowest yield sufficient to sell all the shares being offered at that auction. The buyers pay the sellers the par value; hence holders are virtually assured that their shares can be sold at par. The issuer then must pay a dividend rate over the next 7-week period as determined by the auction. From the holder's standpoint, market auction preferred is a low-risk, largely tax-exempt, 7-week maturity security that can be sold between auction dates at close to par.

In practice, things may not go quite so smoothly. If there are few potential buyers, then an excessively high yield might be required to clear the market. To protect the issuing firms or mutual funds from high dividend payments, the securities have a cap on

[5]Confusingly, market auction preferred stock is frequently referred to as *auction-rate preferred* stock and with the acronym ARP as well.

the allowable dividend yield. If the market-clearing yield is higher than this cap, then the next dividend yield will be set equal to this cap rate, but the auction will fail and the owners of the securities who wish to sell will not be able to do so. This happened in February 2008, and many market auction preferred stockholders were left holding securities they wanted to liquidate.

20-1c Advantages and Disadvantages of Preferred Stock

There are both advantages and disadvantages to financing with preferred stock. Here are the major advantages from the issuer's standpoint.

1. In contrast to bonds, the obligation to pay preferred dividends is not firm, and passing (not paying) a preferred dividend cannot force a firm into bankruptcy.
2. By issuing preferred stock, the firm avoids the dilution of common equity that occurs when common stock is sold.
3. Because preferred stock sometimes has no maturity and because preferred sinking fund payments (if present) are typically spread over a long period, preferred issues reduce the cash flow drain from repayment of principal that occurs with debt issues.

There are two major disadvantages as follows.

1. Preferred stock dividends are not normally deductible to the issuer, so the after-tax cost of preferred is typically higher than the after-tax cost of debt. However, the tax advantage of preferreds to corporate purchasers lowers its pre-tax cost and thus its effective cost.
2. Although preferred dividends can be passed, investors expect them to be paid and firms intend to pay them if conditions permit. Thus, preferred dividends are considered to be a fixed cost. As a result, their use—like that of debt—increases financial risk and hence the cost of common equity.

SELF-TEST

Should preferred stock be classified as equity or debt? Explain.

Who are the major purchasers of nonconvertible preferred stock? Why?

Briefly explain the mechanics of adjustable rate and market auction preferred stock.

What are the advantages and disadvantages of preferred stock to the issuer?

A company's preferred stock has a pre-tax dividend yield of 7%, and its debt has a pre-tax yield of 8%. If an investor is in the 34% marginal tax bracket, what are the after-tax yields of the preferred stock and debt? **(6.29% and 5.28%)**

20-2 Warrants

A **warrant** is a certificate issued by a company that gives the holder the right to buy a stated number of shares of the company's stock at a specified price for some specified length of time. Generally, warrants are issued along with debt, and they are used to induce investors to buy long-term debt with a lower coupon rate than would otherwise be required. For example, when Infomatics Corporation, a rapidly growing high-tech company, wanted to sell $50 million of 20-year bonds in 2015, the company's investment bankers informed the financial vice president that the bonds would be difficult to sell and that a coupon rate of 10% would be required. However, as an alternative the bankers suggested that investors might be willing to buy the bonds with a coupon rate of only 8%

if the company would offer 20 warrants with each $1,000 bond, each warrant entitling the holder to buy one share of common stock at a strike price (also called an *exercise price*) of $22 per share. The stock was selling for $20 per share at the time, and the warrants would expire in the year 2025 if they had not been exercised previously.

Why would investors be willing to buy Infomatics' bonds at a yield of only 8% in a 10% market just because warrants were also offered as part of the package? It's because the warrants are long-term *call options* that allow holders to buy the firm's common stock at the strike price regardless of how high the market price climbs. The value of this option offsets the low interest rate on the bonds and makes the package of low-yield bonds plus warrants attractive to investors. (See Chapter 8 for a discussion of options.)

20-2a Initial Market Price of a Bond with Warrants

If the Infomatics bonds had been issued as straight debt, they would have carried a 10% interest rate. However, with warrants attached, the bonds were sold to yield 8%. Someone buying the bonds at their $1,000 initial offering price would thus be receiving a package consisting of an 8%, 20-year bond plus 20 warrants. Because the going interest rate on bonds as risky as those of Infomatics was 10%, we can find the straight-debt value of the bonds, assuming an annual coupon for ease of illustration, as follows:

Using a financial calculator, input N = 20, I/YR = 10, PMT = 80, and FV = 1000. Then press the PV key to obtain the bond's value of $829.73, or approximately $830. Thus, a person buying the bonds in the initial underwriting would pay $1,000 and receive in exchange a straight bond worth about $830 plus 20 warrants that are presumably worth about $1,000 − $830 = $170:

$$\text{Price paid for bond with warrants} = \text{Straight-debt value of bond} + \text{Value of warrants} \quad (20\text{-}1)$$

$$\$1{,}000 = \$830 + \$170$$

Because investors receive 20 warrants with each bond, each warrant has an implied value of $170/20 = $8.50.

The key issue in setting the terms of a bond-with-warrants deal is valuing the warrants. The straight-debt value can be estimated quite accurately, as we have shown. However, it is more difficult to estimate the value of the warrants. The Black-Scholes option pricing model (OPM), discussed in Chapter 8, can be used to find the value of a call option. There is a temptation to use this model to find the value of a warrant, because call options are similar to warrants in many respects: Both give the investor the right to buy a share of stock at a fixed strike price on or before the expiration date. However, there are major differences between call options and warrants. When call options are exercised, the stock provided to the option holder comes from the secondary market, but when warrants are exercised, the stock provided to the warrant holder is either newly issued shares or treasury stock the company has previously purchased. This means that the exercise of warrants dilutes the value of the original equity, which could cause the value of the original warrant to differ from the value of a similar call option. Also, call options

typically have a life of just a few months, whereas warrants often have lives of 10 years or more. Finally, the Black-Scholes model assumes that the underlying stock pays no dividend, which is not unreasonable over a short period but is unreasonable for 5 or 10 years. Therefore, investment bankers cannot use the original Black-Scholes model to determine the value of warrants.

Even though the original Black-Scholes model cannot be used to determine a precise value for a warrant, there are more sophisticated models that work reasonably well.[6] In addition, investment bankers can simply contact portfolio managers of mutual funds, pension funds, and other organizations that would be interested in buying the securities to get an indication of how many they would buy at different prices. In effect, the bankers hold a presale auction and determine the set of terms that will just clear the market. If they do this job properly then they will, in effect, be letting the market determine the value of the warrants.

20-2b Use of Warrants in Financing

Warrants generally are used by small, rapidly growing firms as **sweeteners** when they sell debt or preferred stock. Such firms frequently are regarded by investors as being highly risky, so their bonds can be sold only at extremely high coupon rates and with very restrictive indenture provisions. To avoid such restrictions, firms like Infomatics often offer warrants along with the bonds.

Getting warrants along with bonds enables investors to share in the company's growth, assuming it does in fact grow and prosper. Therefore, investors are willing to accept a lower interest rate and less restrictive indenture provisions. A bond with warrants has some characteristics of debt and some characteristics of equity. It is a hybrid security that provides the financial manager with an opportunity to expand the firm's mix of securities and thereby appeal to a broader group of investors.

Virtually all warrants issued today are **detachable**. In other words, after a bond with attached warrants is sold, the warrants can be detached and traded separately from the bond. Further, even after the warrants have been exercised, the bond (with its low coupon rate) remains outstanding.

The strike price on warrants is generally set some 20% to 30% above the market price of the stock on the date the bond is issued. If the firm grows and prospers, causing its stock price to rise above the strike price at which shares may be purchased, warrant holders could exercise their warrants and buy stock at the stated price. However, without some incentive, warrants would never be exercised prior to maturity—their value in the open market would be greater than their value if exercised, so holders would sell warrants rather than exercise them. There are three conditions that cause holders to exercise their warrants: (1) Warrant holders will surely exercise and buy stock if the warrants are about

[6]For example, see John C. Hull, *Options, Futures, and Other Derivatives*, 9th ed. (Boston: Prentice-Hall, 2015). Hull shows that if there are m warrants outstanding, each of which can be converted into γ shares of common stock at an exercise price of X, as well as n shares of common stock outstanding, then the price ω of a warrant is given by this modification of the Black-Scholes option pricing formula from Chapter 8:

$$\omega = \left(\frac{n\gamma}{n + m\gamma}\right)[S^*N(d_1^*) - Xe^{-r_{RF}(T-t)}N(d_2^*)] \text{ where } d_1^* = \frac{\ln(S^*/X) + (r_{RF} + \sigma_Q^2/2)(T-t)}{\sigma_Q\sqrt{T-t}}$$

Here $d_2^* = d_1^* - \sigma_Q(T-t)^{1/2}$ and $S^* = S + m\omega/n$, where S is the underlying stock price, T is the maturity date, r_{RF} is the risk free rate, σ_Q is the volatility of the stock and the warrants together, and $N(\cdot)$ is the cumulative normal distribution function. See Chapter 8 for more on the Black-Scholes option pricing formula. If $\gamma = 1$ and n is very much larger than m, so that the number of warrants issued is very small compared to the number of shares of stock outstanding, then this simplifies to the standard Black-Scholes option pricing formula.

to expire and the market price of the stock is above the exercise price. (2) Warrant holders will exercise voluntarily if the company raises the dividend on the common stock by a sufficient amount. No dividend is earned on the warrant, so it provides no current income. However, if the common stock pays a high dividend, then it provides an attractive dividend yield but limits stock price growth. This induces warrant holders to exercise their option to buy the stock. (3) Warrants sometimes have **stepped-up strike prices** (also called stepped-up exercise prices), which prod owners into exercising them. For example, Williamson Scientific Company has warrants outstanding with a strike price of $25 until December 31, 2018, at which time the strike price rises to $30. If the price of the common stock is over $25 just before December 31, 2018, many warrant holders will exercise their options before the stepped-up price takes effect and the value of the warrants falls.

Another desirable feature of warrants is that they generally bring in funds only if funds are needed. If the company grows, it will probably need new equity capital. At the same time, growth will cause the price of the stock to rise and the warrants to be exercised; hence the firm will obtain the cash it needs. If the company is not successful and it cannot profitably employ additional money, then the price of its stock will probably not rise enough to induce exercise of the warrants.

20-2c The Component Cost of Bonds with Warrants

When Infomatics issued its bonds with warrants, the firm received $1,000 for each bond. The pre-tax cost of debt would have been 10% if no warrants had been attached, and this is the component cost of debt that would have been used for calculating the company's weighted average cost of capital as we did in Chapter 9. However, each Infomatics bond has 20 warrants, each of which entitles its holder to buy one share of stock for $22. The presence of warrants also allows Infomatics to pay only 8% interest on the bonds, obligating it to pay $80 interest for 20 years plus $1,000 at the end of 20 years. So given these complicating factors, what is the component cost of capital for bonds with warrants? As we shall see, the cost is well above the 8% coupon rate on the bonds and is also above the 10% cost if the company had issued straight debt.

The best way to approach this analysis is to break the $1,000 bond with warrants attached into two components, one consisting of an $830 bond and the other consisting of $170 of warrants, and calculate the cost of capital for each of these components. Thus, the $1,000 bond-with-warrants package consists of $830/$1,000 = 0.83 = 83% straight debt and $170/$1,000 = 0.17 = 17% warrant. We will find the cost of capital for the straight bonds and the cost of capital for the warrant, and then weight them to derive the cost of capital for the bond-with-warrants package.

Finding the cost of capital for the straight bond component is easy. The pre-tax component cost of debt is 10% because this is the pre-tax cost of debt for a straight bond. Estimating the cost of capital for the warrant component, however, is fairly complicated in theory, but we can use the following simplified procedure to obtain a reasonable approximation.[7] The basic idea is to estimate the firm's expected dollar cost of satisfying the warrant holders at the time the warrants expire and use this to calculate the warrant holders' expected return from owning the warrants. This expected return will be our component cost of capital for the warrants.

To calculate the firm's expected cost of satisfying the warrants, we need an estimate of the value of the firm's stock price on the warrants' expiration date, T. From the free cash

[7]For an exact solution, see P. Daves and M. Ehrhardt, "Convertible Securities, Employee Stock Options, and the Cost of Equity," *The Financial Review*, Vol. 42, 2007, pp. 267–288.

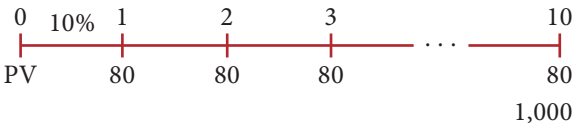
flow valuation model in Chapter 7, this price will be the expected intrinsic value of the total firm less the value of the debt, all divided by the number of shares. Each of these three pieces is estimated for the date the warrants expire, T:



$$\text{Estimated price of stock}_T = \frac{\text{Intrinsic value of equity}_T}{\text{Shares outstanding}_T}$$

$$= \frac{\text{Estimated total value of firm}_T - \text{Estimated value of debt}_T}{\text{Shares outstanding}_T}$$

Assume that the total value of Infomatics' operations and investments, which is $250 million immediately after issuing the bonds with warrants, is expected to grow at 9% per year. When the warrants are due to expire in 10 years, the total value of Infomatics is expected to be $\$250(1.09)^{10} = \$591.841$ million.

Infomatics will receive $22 per warrant when exercised; with 1 million warrants, this creates a $22 million cash flow to Infomatics. The total value of Infomatics will be equal to the value of operations plus the value of this cash. This will make the total value of Infomatics equal to $\$591.84 + \$22 = \$613.841$ million.

When the warrants expire, the bonds will have 10 more years remaining until maturity with a fixed coupon payment of $80. If the expected market interest rate is still 10%, then the time line of cash flows will be:

Using a financial calculator, input N = 10, I/YR = 10, PMT = 80, and FV = 1000; then press the PV key to obtain the bond's value, $877.11. The total value of all of the bonds is therefore expected to be $50{,}000(\$877.11) = \$43.856$ million.

The intrinsic value of equity is equal to the total value of the firm minus the value of debt: $\$613.841 - \$43.856 = \$569.985$ million.

Infomatics had 10 million shares outstanding prior to the warrants' exercise, so it will have 11 million after the 1 million options are exercised. The predicted intrinsic stock price is equal to the intrinsic value of equity divided by the number of shares: $\$569.985/11 = \$51.82$ per share.[8] These calculations are summarized in Table 20-1.

To find the component cost of the warrants, consider that Infomatics will have to issue one share of stock worth $51.82 for each warrant exercised and, in return, Infomatics will receive the strike price from the warrant holder, $22. Thus, a purchaser of the bonds with warrants, if she holds the complete package, would expect to realize a profit in Year 10 of $\$51.82 - \$22 = \$29.82$ for each warrant exercised.[9] Because each bond has 20 warrants attached and because each warrant entitles the holder to buy one share of common stock, it follows that warrant holders will have an expected cash flow of

[8]If the stock price had been less than the strike price of $22 at expiration, then the warrants would not have been exercised. Based on the expected growth in the firm's value, there is little chance that the stock price will not be greater than $22.

[9]It is not strictly accurate to say that the expected profit from the warrant position is the expected stock price less the strike price: $\$29.82 = \$51.82 - \$22$. This is because if the stock price drops below the strike price, in this case $22, then the warrant profit is $0, regardless of how low the stock price goes. Thus, the expected payoff will be somewhat more than $29.82. Although this expectation can be calculated using options techniques similar to those in Chapter 8, it is beyond the scope of this chapter. However, if there is a very small probability that the stock price will drop below the exercise price, then $29.82 is very close to the true expected payoff.

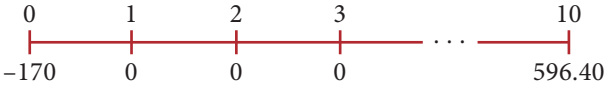
TABLE 20-1
Valuation Analysis after Exercise of Warrants in 10 Years (Millions of Dollars, Except for Per Share Data)

	Warrants Are Exercised
Expected value of operations and investments[a]	$591.841
Plus new cash from exercise of warrants[b]	22.000
Total value of firm	$613.841
Minus value of bonds	43.856
Value remaining for shareholders	$569.985
Divided by shares outstanding[c]	11
Price per share	$ 51.82



Notes:

[a] The value of operations and investments is expected to grow from its current $250 million at a rate of 9%: $\$250(1.09)^{10} = \$591.841$ million.

[b] The warrants will be exercised only if the stock price at expiration is above $22. If the stock price is less than $22, then the warrants will expire worthless and there will be no new capital. Our calculations show that the expected stock price is much greater than $22, so the warrants are expected to be exercised.

[c] Before the warrants are exercised, there are 10 million shares of stock. After the warrants are exercised, there will be $10 + 1 = 11$ million shares outstanding.

$20(\$29.82) = \$596.40$ per bond at the end of Year 10. Here is a time line of the expected cash flow stream to a warrant holder:

The IRR of this stream is 13.35%, which is an approximation of the warrant holder's expected return on the warrants (r_w) in the bond with warrants. The overall pre-tax cost of capital for the bonds with warrants is the weighted average of the cost of straight debt and the cost of warrants:

$$\begin{aligned}\text{Pre-tax cost of bonds with warrants} &= r_d(\$830/\$1{,}000) + r_w(\$170/\$1{,}000)\\ &= 10\%(0.83) + 13.35\%(0.17) = 10.57\%\end{aligned}$$

The cost of the warrants is higher than the cost of debt because warrants are riskier than debt; in fact, the cost of warrants is greater than the cost of equity because warrants also are riskier than equity. Thus, the cost of capital for a bond with warrants is somewhere between the cost of debt and the much higher cost of equity. This means the overall cost of capital for the bonds with warrants will be greater than the cost of straight debt and will be much higher than the 8% coupon rate on the bonds-with-warrants package.[10]

Bonds with warrants and preferred stock with warrants have become an important source of funding for companies during the global economic crisis. But as our example

[10] In order to estimate the after-tax cost of capital, the after-tax cost of each component must be estimated. The after-tax cost of the warrant is the same as the pre-tax cost because warrants do not affect the issuer's tax liability. This is not true for the bond component. ***Web Extension 5A*** on the textbook's Web site shows that the after-tax cost of debt when the bond is issued at a price less than par is equal to the yield on that debt multiplied by 1–T, just like when the bond is issued at par. Thus the after-tax cost of Infomatics' bond component is $10\%(1 - 0.40) = 6\%$, assuming a 40% tax rate. We also show this calculation as well as the complete after-tax cost of capital calculation for the bonds with warrants attached in the ***Ch20 Tool Kit.xlsx***.

shows, this form of financing has a much higher cost of capital than its low coupon and preferred dividend might lead you to think.[11]

SELF-TEST

What is a warrant?

Describe how a new bond issue with warrants is valued.

How are warrants used in corporate financing?

The use of warrants lowers the coupon rate on the corresponding debt issue. Does this mean that the component cost of a debt-plus-warrants package is less than the cost of straight debt? Explain.

Shanton Corporation could issue 15-year straight debt at a rate of 8%. Instead, Shanton issues 15-year debt with a coupon rate of 6%, but each bond has 25 warrants attached. The bonds can be issued at par ($1,000 per bond). Assuming annual interest payments, what is the implied value of each warrant? **($6.85)**

20-3 Convertible Securities

Convertible securities are bonds or preferred stocks that, under specified terms and conditions, can be exchanged for (that is, converted into) common stock at the option of the holder. Unlike the exercise of warrants, which brings in additional funds to the firm, conversion does not provide new capital; debt (or preferred stock) is simply replaced on the balance sheet by common stock. Of course, reducing the debt or preferred stock will improve the firm's financial strength and make it easier to raise additional capital, but that requires a separate action.

20-3a Conversion Ratio and Conversion Price

resource

*See **Ch20 Tool Kit.xlsx** on the textbook's Web site for details.*

The **conversion ratio (CR)** is defined as the number of shares of stock a bondholder will receive upon conversion. The **conversion price (P_c)** is defined as the effective price investors pay for the common stock when conversion occurs. The relationship between the conversion ratio and the conversion price can be illustrated by Silicon Valley Software Company's convertible debentures issued at their $1,000 par value in July of 2015. At any time prior to maturity on July 15, 2035, a debenture holder can exchange a bond for 18 shares of common stock. Therefore, the conversion ratio, CR, is 18. The bond cost a purchaser $1,000, the par value, when it was issued. Dividing the $1,000 par value by the 18 shares received gives a conversion price of $55.56 a share:

$$\text{Conversion price} = P_c = \frac{\text{Par value of bond given up}}{\text{Shares received}} \quad (20\text{-}2)$$

$$= \frac{\$1{,}000}{CR} = \frac{\$1{,}000}{18} = \$55.56$$

[11]For more on warrant pricing, see Michael C. Ehrhardt and Ronald E. Shrieves, "The Impact of Warrants and Convertible Securities on the Systematic Risk of Common Equity," *Financial Review*, November 1995, pp. 843–856; Beni Lauterbach and Paul Schultz, "Pricing Warrants: An Empirical Study of the Black-Scholes Model and Its Alternatives," *Journal of Finance*, September 1990, pp. 1181–1209; David C. Leonard and Michael E. Solt, "On Using the Black-Scholes Model to Value Warrants," *Journal of Financial Research*, Summer 1990, pp. 81–92; and Katherine L. Phelps, William T. Moore, and Rodney L. Roenfeldt, "Equity Valuation Effects of Warrant-Debt Financing," *Journal of Financial Research*, Summer 1991, pp. 93–103.

Conversely, by solving for CR, we obtain the conversion ratio:

$$\text{Conversion ratio} = \text{CR} = \frac{\$1{,}000}{P_c} \tag{20-3}$$

$$= \frac{\$1{,}000}{\$55.56} = 18 \text{ Shares}$$

Once CR is set, the value of P_c is established, and vice versa.

Like a warrant's exercise price, the conversion price is typically set some 20% to 30% above the prevailing market price of the common stock on the issue date. Generally, the conversion price and conversion ratio are fixed for the life of the bond, with the exception of protection against dilutive actions the company might take, including stock splits, stock dividends, and the sale of common stock at prices below the conversion price.[12]

The typical protective provision states that if the stock is split or if a stock dividend is declared, the conversion price must be lowered by the percentage amount of the stock dividend or split. For example, if Silicon Valley Software (SVS) were to have a 2-for-1 stock split, then the conversion ratio would automatically be adjusted from 18 to 36 and the conversion price lowered from $55.56 to $27.73. Also, if SVS sells common stock at a price below the conversion price, then the conversion price must be lowered (and the conversion ratio raised) to the price at which the new stock is issued. If protection were not contained in the contract, then a company could always prevent conversion by the use of stock splits and stock dividends. Warrants have similar protection against dilution.

However, this standard protection against dilution from selling new stock at prices below the conversion price can get a company into trouble. For example, SVS's stock was selling for $35 per share at the time the convertible was issued. Now suppose that the market went sour and the stock price dropped to $15 per share. If SVS needs new equity to support operations, a new common stock sale would require the company to lower the conversion price on the convertible debentures from $55.56 to $15. What impact would this have on the existing shareholders?

First, think about the value of a convertible bond as consisting of a straight bond and an option to convert. Reducing the conversion price is like reducing the strike price on an option, which would make the option to convert much more valuable. Second, recall the approach taken by the free cash flow valuation model to determine the value of equity—start with the value of operations, add the value of any non-operating assets (like T-bills), and subtract the value of any debt, including convertible bonds. We can estimate the value of equity at the original conversion price and compare it to the value of equity at the new conversion price. At the new conversion price, the value of the convertible bond goes up, so the value of equity goes down, causing a transfer of wealth from the existing shareholders to the convertible bondholders. Therefore, the protective reset feature on the conversion price makes it very costly for existing shareholders to raise additional equity in the times when new equity is needed.

[12]Some convertible bonds have a stepped-up conversion price. For example, a convertible bond might be convertible into 12 shares for the first 10 years, into 11 shares for the next 10, and 10 shares for the remainder of its life. This has the effect of increasing the conversion price over time, so that the holder of a convertible bond won't get rewarded if the stock price grows slowly.

20-3b The Component Cost of Convertibles

resource

*See **Ch20 Tool Kit.xlsx** on the textbook's Web site for details.*

In the spring of 2015, Silicon Valley Software was evaluating the use of the convertible bond issue described earlier. The issue would consist of 20-year convertible bonds that would sell at a price of $1,000 per bond; this $1,000 would also be the bond's par (and maturity) value. The bonds would pay an 8% annual coupon interest rate, which is $80 per year. Each bond would be convertible into 18 shares of stock, so the conversion price would be $1,000/18 = $55.56. Its stock price was $35. If the bonds were not made convertible then they would have to provide a yield of 10%, given their risk and the general level of interest rates. The convertible bonds would not be callable for 10 years, after which they could be called at a price of $1,050, with this price declining by $5 per year thereafter. If, after 10 years, the conversion value exceeded the call price by at least 20%, management would probably call the bonds.

resource

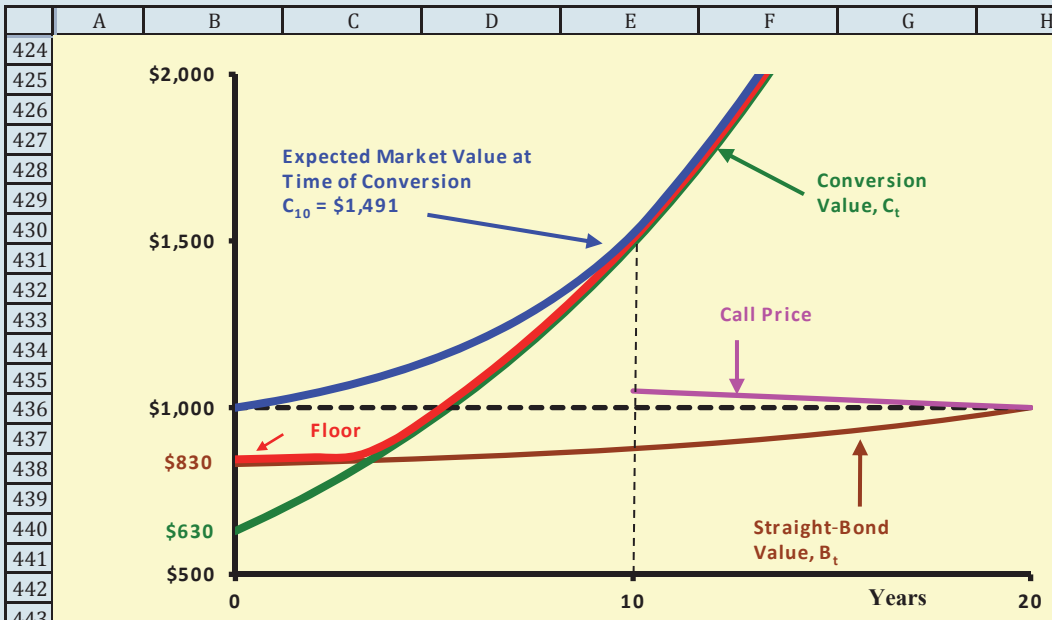
*For a more detailed discussion of call strategies, see **Web Extension 20A** on the textbook's Web site.*

SVS's cost of equity is 13%, with a 4% dividend yield and expected capital gain of 9% per year (Silicon Valley Software is a high-risk company with low dividends and occasional stock repurchases, so its stock price has a high expected growth rate).

Figure 20-1 shows the expectations of both an average investor and the company. Refer to the figure as you consider the following points:

1. The horizontal dashed line at $1,000 represents the par (and maturity) value. Also, $1,000 is the price at which the bond is initially offered to the public.
2. The bond is protected against a call for 10 years. It is initially callable at a price of $1,050; the call price declines thereafter by $5 per year, as shown by the pink line in Figure 20-1.
3. Because the convertible has an 8% coupon rate and because the yield on a nonconvertible bond of similar risk is 10%, it follows that the expected "straight-bond" value of the convertible, B_t, must be less than par. At the time of issue and assuming an annual coupon, B_0 is $830:

$$\text{Straight-debt value at time of issue} = B_0 = \sum_{t=1}^{N} \frac{\text{Coupon interest}}{(1+r_d)^t} + \frac{\text{Maturity value}}{(1+r_d)^N} \quad \textbf{(20-4)}$$



$$= \sum_{t=1}^{20} \frac{\$80}{(1.10)^t} + \frac{\$1{,}000}{(1.10)^{20}} = \$830$$

Note, however, that the bond's straight-debt value must be $1,000 at maturity, so the straight-debt value rises over time; this is plotted by the brown line in Figure 20-1.

4. The bond's initial **conversion value, C**, or the value of the stock an investor would receive if the bonds were converted at t = 0, is $P_0(CR) = \$35(18 \text{ shares}) = \$630$. Because the stock price is expected to grow at a 9% rate, the conversion value should rise over time. For example, in Year 5 it should be $P_5(CR) = \$35(1.09)^5(18) = \$969$. The expected conversion value is shown by the green line in Figure 20-1.
5. If the market price dropped below the straight-bond value, then those who wanted bonds would recognize the bargain and buy the convertible as a bond. Similarly, if the market price dropped below the conversion value, people would buy the convertibles, exercise them to get stock, and then sell the stock at a profit. Therefore, the higher of the bond value and conversion value curves in the graph represents a *floor price* for the bond. In Figure 20-1, the floor price is represented by the red line.

6. The convertible bond's market price will exceed the straight-bond value because the option to convert is worth something—an 8% bond with conversion possibilities is worth more than an 8% bond without this option. The convertible's price will also exceed its conversion value because holding the convertible is equivalent to holding a call option and, prior to expiration, the option's true value is higher than its exercise (or conversion) value. Without using financial engineering models, we cannot say exactly where the market value line will lie, but as a rule it will be above the floor, as shown by the blue line in Figure 20-1.

7. If the stock price continues to increase, then it becomes more and more likely that the bond will be converted. As this likelihood increases, the market value line will begin to converge with the conversion value line.

   After the bond becomes callable, its market value cannot exceed the higher of the conversion value and the call price without exposing investors to the danger of a call. For example, suppose that 10 years after issue (when the bonds become callable) the market value of the bond is $1,600, the conversion value is $1,500, and the call price is $1,050. If the company called the bonds the day after you bought one for $1,600, you would choose to convert them to stock worth only $1,500 (rather than let the company buy the bond from you at the $1,050 call price), so you would suffer a loss of $100. Recognizing this danger, you and other investors would refuse to pay a premium over the higher of the call price or the conversion value after the bond becomes callable. Therefore, in Figure 20-1, we assume that the market value line hits the conversion value line in Year 10, when the bond becomes callable.
8. In our example, the call-protection period ends in 10 years. At this time, the expected stock price is so high that the conversion value is almost certainly going to be greater than the call price; hence, we assume that the bond will be converted immediately prior to the company calling the bond, which would happen in 10 years.
9. The expected market value at Year 10 is $\$35(1.09)^{10}(18) = \$1{,}491$. An investor can find the expected rate of return on the convertible bond, r_c, by finding the IRR of the following cash flow stream:

   With a financial calculator, we set N = 10, PV = −1000, PMT = 80, and FV = 1491; we then solve for $I/YR = r_c = IRR = 10.94\%$.[13]
10. A convertible bond is riskier than straight debt but less risky than stock, so its cost of capital should be somewhere between the cost of straight debt and the cost of equity. This is true in our example: $r_d = 10\%$, $r_c = 10.94\%$, and $r_s = 13\%$.[14]

[13]As in the case with warrants, the expected conversion value is not precisely equal to the expected stock price multiplied by the conversion ratio. Here is the reason: If after 10 years the stock price happens to be low, so that the conversion value is less than the call price, then the bondholders would not choose to convert—instead, they would surrender their bonds if the company called them. In this example, conversion does not occur if the stock price is less than $\$1{,}050/18 = \$58.33$ after 10 years. Because the company makes a call in order to force conversion, it won't call the bonds if the stock price is less than $58.33. So when the stock price is low, the bondholders will keep the bonds, whose value will depend primarily on interest rates at that time. Finding the expected value in this situation is a difficult problem (and is beyond the scope of this text). However, if the expected stock price is much greater than the conversion price when the bonds are called (in this case, $35[1.09]^{10} = \$82.86$ is much more than $58.33), then the difference between the true expected conversion value and the conversion value that we calculated using the expected stock price will be very small. Therefore, we can approximate the component cost reasonably accurately with the approach used in the example.

[14]To find the after-tax cost of the convertible, you can replace the pre-tax coupons with the after-tax coupons paid by the company. If the corporate tax rate is 40%, then we have N = 10, PV = −1000, $PMT = 80(1 - 0.40) = 48$, and FV = 1491; we solve for $I/YR = r_{c,AT} = 8.16\%$. Notice that this after-tax cost is not equal to $r_c(1 - T)$. Note also that this tax treatment is different from that of bonds with warrants as discussed earlier in this chapter. The company receives no tax benefits from the conversion feature in convertible bonds.

20-3c Use of Convertibles in Financing

Convertibles have two important advantages from the issuer's standpoint: (1) Convertibles, like bonds with warrants, offer a company the chance to sell debt with a low coupon rate in exchange for giving bondholders a chance to participate in the company's success if it does well. (2) In a sense, convertibles provide a way to sell common stock at prices higher than those currently prevailing. Some companies actually want to sell common stock, not debt, but feel that the price of their stock is temporarily depressed. Management may know, for example, that earnings are depressed because of start-up costs associated with a new project, but they expect earnings to rise sharply during the next year or so, pulling the price of the stock up with them. Thus, if the company sold stock now, it would be giving up more shares than necessary to raise a given amount of capital. However, if it set the conversion price 20% to 30% above the present market price of the stock, then 20% to 30% fewer shares would be given up when the bonds were converted than if stock were sold directly at the current time. Note, however, that management is counting on the stock's price to rise above the conversion price, thus making the bonds attractive in conversion. If earnings do not rise and pull the stock price up, so that conversion does *not* occur, then the company will be saddled with debt in the face of low earnings, which could be disastrous. How can the company be sure that conversion will occur if the price of the stock rises above the conversion price? Typically, convertibles contain a call provision that enables the issuing firm to force holders to convert. Suppose the conversion price is \$50, the conversion ratio is 20, the market price of the common stock has risen to \$60, and the call price on a convertible bond is \$1,050. If the company calls the bond, bondholders can either convert into common stock with a market value of $20(\$60) = \$1{,}200$ or allow the company to redeem the bond for \$1,050. Naturally, bondholders prefer \$1,200 to \$1,050, so conversion would occur. The call provision thus gives the company a way to force conversion, provided the market price of the stock is greater than the conversion price. Note, however, that most convertibles have a fairly long period of call protection—10 years is typical. Therefore, if the company wants to be able to force conversion early, it will have to set a short call-protection period. This will, in turn, require that it set a higher coupon rate or a lower conversion price.

From the standpoint of the issuer, convertibles have three important disadvantages: (1) Even though the use of a convertible bond may give the company the opportunity to sell stock at a price higher than the current price, if the stock greatly increases in price then, the firm would be better off if it had used straight debt (in spite of its higher cost) and then later sold common stock and refunded the debt. (2) Convertibles typically have a low coupon interest rate, and the advantage of this low-cost debt will be lost when conversion occurs. (3) If the company truly wants to raise equity capital and if the price of the stock does not rise sufficiently after the bond is issued, then the company will be stuck with debt.

20-3d Convertibles and Agency Costs

A potential agency conflict between bondholders and stockholders is asset substitution, also known as "bait and switch." Suppose a company has been investing in low-risk projects, and because risk is low, bondholders charge a low interest rate. What happens if the company is considering a very risky but highly profitable venture that potential lenders don't know about? The company might decide to raise low-interest-rate debt without revealing that the funds will be invested in a risky project. After the funds have been raised and the investment is made, the value of the debt should fall because its interest rate will be too low to compensate debtholders for the high risk they bear. This is a "heads I win, tails you lose" situation, and it results in a wealth transfer from bondholders to stockholders.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Let's use some numbers to illustrate this scenario. The value of a company, based on the present value of its future free cash flows, is $800 million. It has $300 million of debt, based on market values. Therefore, its equity is worth $800 − $300 = $500 million. The company now undertakes some projects with high but risky expected returns, and its expected NPV remains unchanged. In other words, the actual NPV will probably end up much higher or much lower than under the old situation, but the firm still has the same expected value. Even though its total value is still $800 million, the value of the debt falls because its risk has increased. Note that the debtholders don't benefit if the venture's value is higher than expected, because the most they can receive is the contracted coupon and the principal repayment. However, they will suffer if the value of the projects turns out to be lower than expected, because they might not receive the full value of their contracted payments. In other words, risk doesn't give them any upside potential but does expose them to downside losses, so the bondholders' expected value must decline.

With a constant total firm value, if the value of the debt falls from $300 to $200 million, then the value of equity must increase from $500 to $800 − $200 = $600 million. Thus, the bait-and-switch tactic causes a wealth transfer of $100 million from debtholders to stockholders.

If debtholders think a company might employ the bait-and-switch tactic, they will charge a higher interest rate, and this higher interest rate is an agency cost. Debtholders will charge this higher rate even if the company has no intention of engaging in bait-and-switch behavior, because they can't know the company's true intentions. Therefore, they assume the worst and charge a higher interest rate.

Convertible securities are one way to mitigate this type of agency cost. Suppose the debt is convertible and the company does take on the high-risk project. If the value of the company turns out to be higher than expected, then bondholders can convert their debt to equity and benefit from the successful investment. Therefore, bondholders are willing to charge a lower interest rate on convertibles, and this serves to minimize the agency costs.

Note that if a company does not engage in bait-and-switch behavior by swapping low-risk projects for high-risk projects, then the chance of "hitting a home run" is reduced. Because there is less chance of a home run, the convertible bond is less likely to be converted. In this situation, the convertible bonds are actually similar to nonconvertible debt, except that they carry a lower interest rate.

Now consider a different agency cost, one due to asymmetric information between the managers and potential new stockholders. Suppose a firm's managers know that its future prospects are not as good as the market believes, which means the current stock price is too high. Acting in the interests of existing stockholders, managers can issue stock at the current high price. When the poor future prospects are eventually revealed, the stock price will fall, causing a transfer of wealth from the new shareholders to old shareholders.

To illustrate this, suppose the market estimates an $800 million present value of future free cash flows. For simplicity, assume the firm has no nonoperating assets and no debt, so the total value of both the firm and the equity is $800 million. However, its managers know the market has overestimated the future free cash flows and that the true value is only $700 million. When investors eventually discover this, the value of the company will drop to $700 million. But before this happens, suppose the company raises $200 million of new equity. The company uses this new cash to invest in projects with a present value of $200 million, which shouldn't be too hard, because these projects have a zero NPV. Right after the new stock is sold, the company will have a market value of $800 + $200 = $1,000 million, based on the market's overly optimistic estimate of the company's future prospects. Observe that the new shareholders own 20% of the company ($200/$1,000 = 0.20) and the original shareholders own 80%.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

As time passes, the market will realize that the previously estimated value of $800 million for the company's original set of projects was too high and that these projects are worth only $700 million. The new projects are still worth $200 million, so the total value of the company will fall to $700 + $200 = $900 million. The original shareholders' value is now 80% of $900 million, which is $720 million. Note that this is $20 million *more* than it would have been if the company had issued no new stock. The new shareholders' value is now $0.20(\$900) = \$180$ million, which is $20 million *less* than their original investment. The net effect is a $20 million wealth transfer from the new shareholders to the original shareholders.

Because potential shareholders know this might occur, they interpret an issue of new stock as a signal of poor future prospects, which causes the stock price to fall. Note also that this will occur even for companies whose future prospects are actually quite good, because the market has no way of distinguishing between companies with good versus poor prospects.

A company with good future prospects might want to issue equity, but it knows the market will interpret this as a negative signal. One way to obtain equity and yet avoid this signaling effect is to issue convertible bonds. Because the company knows its true future prospects are better than the market anticipates, it knows the bonds will likely end up being converted to equity. Thus, a company in this situation is issuing equity "through the back door" when it issues convertible debt.

In summary, convertibles are logical securities to use in at least two situations. First, if a company would like to finance with straight debt but lenders are afraid the funds will be invested in a manner that increases the firm's risk profile, then convertibles are a good choice. Second, if a company wants to issue stock but thinks such a move would cause investors to interpret a stock offering as a signal of tough times ahead, then again convertibles would be a good choice.[15]

What is a conversion ratio? A conversion price? A straight-bond value?

What is meant by a convertible's floor value*?*

What are the advantages and disadvantages of convertibles to issuers? To investors?

How do convertibles reduce agency costs?

A convertible bond has a par value of $1,000 and a conversion price of $25. The stock currently trades for $22 a share. What are the bond's conversion ratio and conversion value at t = 0? **(40, $880)**

20-4 A Final Comparison of Warrants and Convertibles

Convertible debt can be thought of as straight debt with nondetachable warrants. Thus, at first blush, it might appear that debt with warrants and convertible debt are more or less interchangeable. However, a closer look reveals one major and several minor differences

[15]See Craig M. Lewis, Richard J. Rogalski, and James K. Seward, "Understanding the Design of Convertible Debt," *Journal of Applied Corporate Finance*, Vol. 11, No. 1, Spring 1998, pp. 45–53. For more insights into convertible pricing and use, see Paul Asquith and David W. Mullins Jr., "Convertible Debt: Corporate Call Policy and Voluntary Conversion," *Journal of Finance*, September 1991, pp. 1273–1289; Randall S. Billingsley and David M. Smith, "Why Do Firms Issue Convertible Debt?" *Financial Management*, Summer 1996, pp. 93–99; Douglas R. Emery, Mai E. Iskandor-Datta, and Jong-Chul Rhim, "Capital Structure Management as a Motivation for Calling Convertible Debt," *Journal of Financial Research*, Spring 1994, pp. 91–104; T. Harikumar, P. Kadapakkam, and Ronald F. Singer, "Convertible Debt and Investment Incentives," *Journal of Financial Research*, Spring 1994, pp. 15–29; and V. Sivarama Krishnan and Ramesh P. Rao, "Financial Distress Costs and Delayed Calls of Convertible Bonds," *Financial Review*, November 1996, pp. 913–925.

between these two securities.[16] First, as we discussed previously, the exercise of warrants brings in new equity capital, whereas the conversion of convertibles results only in an accounting transfer.

A second difference involves flexibility. Most convertibles contain a call provision that allows the issuer either to refund the debt or to force conversion, depending on the relationship between the conversion value and call price. However, most warrants are not callable, so firms must wait until maturity for the warrants to generate new equity capital. Generally, maturities also differ between warrants and convertibles. Warrants typically have much shorter maturities than convertibles, and warrants typically expire before their accompanying debt matures. Warrants also provide for fewer future common shares than do convertibles, because with convertibles all of the debt is converted to stock, whereas debt remains outstanding when warrants are exercised. Together, these facts suggest that debt-plus-warrant issuers are actually more interested in selling debt than in selling equity.

In general, firms that issue debt with warrants are smaller and riskier than those that issue convertibles. One possible rationale for the use of option securities, especially the use of debt with warrants by small firms, is the difficulty investors have in assessing the risk of small companies. If a start-up with a new, untested product seeks debt financing, then it's difficult for potential lenders to judge the riskiness of the venture and so it's difficult to set a fair interest rate. Under these circumstances, many potential investors will be reluctant to invest, making it necessary to set a very high interest rate to attract debt capital. By issuing debt with warrants, investors obtain a package that offers upside potential to offset the risks of loss.

Finally, there is a significant difference in issuance costs between debt with warrants and convertible debt. Bonds with warrants typically require issuance costs that are about 1.2 percentage points more than the flotation costs for convertibles. In general, bond-with-warrant financings have underwriting fees that approximate the weighted average of the fees associated with debt and equity issues, whereas underwriting costs for convertibles are more like those associated with straight debt.

SELF-TEST

What are some differences between debt-with-warrant financing and convertible debt?

Explain how bonds with warrants might help small, risky firms sell debt securities.

20-5 Reporting Earnings When Warrants or Convertibles Are Outstanding

If warrants or convertibles are outstanding, the Financial Accounting Standard Board requires that a firm report basic earnings per share and diluted earnings per share.[17]

[16]For a more detailed comparison of warrants and convertibles, see Michael S. Long and Stephen F. Sefcik, "Participation Financing: A Comparison of the Characteristics of Convertible Debt and Straight Bonds Issued in Conjunction with Warrants," *Financial Management*, Autumn 1990, pp. 23–34.

[17]FAS 128 was issued in February of 1997. It simplified the calculations required by firms, made U.S. standards more consistent with international standards, and required the presentation of both basic EPS and diluted EPS for those firms with significant amounts of convertible securities. In addition, it replaced a measure called *primary EPS* with basic EPS. In general, the calculation of primary EPS required the company to estimate whether or not a security was "likely to be converted in the near future" and to base the calculation of EPS on the assumption that those securities would in fact have been converted. In June 2008 the FASB issued FSP APB 14-1, which (although not changing how EPS is reported under FAS 128) requires that convertibles be split into their implied equity and debt components for accounting purposes, in much the same way as we analyze them in this chapter.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

1. *Basic* EPS is calculated as earnings available to common stockholders divided by the average number of shares actually outstanding during the period.
2. *Diluted* EPS is calculated as the earnings that would have been available to common shareholders divided by the average number of shares that would have been outstanding if "dilutive" securities had been converted. The rules governing the calculation of diluted EPS are quite complex; here we present a simple illustration using convertible bonds. If the bonds had been converted at the beginning of the accounting period, then the firm's interest payments would have been lower because it would not have had to pay interest on the bonds, and this would have caused earnings to be higher. But the number of outstanding shares of stock also would have increased because of the conversion. If the higher earnings and higher number of shares caused EPS to fall, then the convertible bonds would be defined as dilutive securities because their conversion would decrease (or dilute) EPS. All convertible securities with a net dilutive effect are included when calculating diluted EPS. Therefore, this definition means that diluted EPS always will be lower than basic EPS. In essence, the diluted EPS measure is an attempt to show how the presence of convertible securities reduces common shareholders' claims on the firm.

Under SEC rules, firms are required to report both basic and diluted EPS. For firms with large amounts of option securities outstanding, there can be a substantial difference between the basic and diluted EPS figures. This makes it easier for investors to compare the performance of U.S. firms with their foreign counterparts, which tend to use basic EPS.

SELF-TEST

What are the three possible methods for reporting EPS when warrants and convertibles are outstanding?

Which methods are most used in practice?

Why should investors be concerned about a firm's outstanding warrants and convertibles?

SUMMARY

Although common stock and long-term debt provide most of the capital used by corporations, companies also use several forms of "hybrid securities." The hybrids include preferred stock, convertibles, and warrants, and they generally have some characteristics of debt and some of equity. The key concepts covered are listed below.

- **Preferred stock** is a hybrid—it is similar to bonds in some respects and to common stock in other ways.
- **Adjustable rate preferred stocks (ARPs)** pay dividends tied to the rate on Treasury securities. **Market auction (money market) preferred stocks** are low-risk, largely tax-exempt securities of 7-week maturity that can be sold between auction dates at close to par.
- A **warrant** is a long-term call option issued along with a bond. Warrants are generally detachable from the bond, and they trade separately in the market. When warrants are exercised, the firm receives additional equity capital, and the original bonds remain outstanding.
- A **convertible security** is a bond or preferred stock that can be exchanged for common stock at the option of the holder. When a security is converted, debt or preferred stock is replaced with common stock, and no money changes hands.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- Warrant and convertible issues generally are structured so that the **strike price** (also called the **exercise price**) or **conversion price** is 20% to 30% above the stock's price at time of issue.
- Although both warrants and convertibles are option securities, there are several differences between the two, including separability, impact when exercised, callability, maturity, and flotation costs.
- Warrants and convertibles are **sweeteners** used to make the underlying debt or preferred stock issue more attractive to investors. Although the coupon rate or dividend yield is lower when options are part of the issue, the overall cost of the issue is higher than the cost of straight debt or preferred, because option-related securities are riskier.
- For a more detailed discussion of call strategies, see ***Web Extension 20A*** on the textbook's Web site.

QUESTIONS

(20-1) Define each of the following terms:

a. Preferred stock
b. Cumulative dividends; arrearages
c. Warrant; detachable warrant
d. Stepped-up price
e. Convertible security
f. Conversion ratio; conversion price; conversion value
g. Sweetener

(20-2) Is preferred stock more like bonds or common stock? Explain.

(20-3) What effect does the trend in stock prices (subsequent to issue) have on a firm's ability to raise funds through: (a) convertibles and (b) warrants?

(20-4) If a firm expects to have additional financial requirements in the future, would you recommend that it use convertibles or bonds with warrants? What factors would influence your decision?

(20-5) How does a firm's dividend policy affect each of the following?

a. The value of its long-term warrants
b. The likelihood that its convertible bonds will be converted
c. The likelihood that its warrants will be exercised

(20-6) Evaluate the following statement: "Issuing convertible securities is a means by which a firm can sell common stock for more than the existing market price."

(20-7) Suppose a company simultaneously issues $50 million of convertible bonds with a coupon rate of 10% and $50 million of straight bonds with a coupon rate of 14%. Both bonds have the same maturity. Does the convertible issue's lower coupon rate suggest that it is less risky than the straight bond? Is the cost of capital lower on the convertible than on the straight bond? Explain.

SELF-TEST PROBLEM

Solution Shown in Appendix A

(ST-1) Warrants

Connor Company recently issued two types of bonds. The first issue consisted of 10-year straight debt with a 6% annual coupon. The second issue consisted of 10-year bonds with a 4.5% annual coupon and attached warrants. Both issues sold at their $1,000 par values. What is the implied value of the warrants attached to each bond?

PROBLEMS

Answers Are in Appendix B

EASY PROBLEMS 1–2

(20-1) Warrants

Neubert Enterprises recently issued $1,000 par value 15-year bonds with a 5% coupon paid annually and warrants attached. These bonds are currently trading for $1,000. Neubert also has outstanding $1,000 par value 15-year straight debt with a 7% coupon paid annually, also trading for $1,000. What is the implied value of the warrants attached to each bond?

(20-2) Convertibles

Breuer Investment's convertible bonds have a $1,000 par value and a conversion price of $50 a share. What is the convertible issue's conversion ratio?

INTERMEDIATE PROBLEMS 3–4

(20-3) Warrants

Maese Industries Inc. has warrants outstanding that permit the holders to purchase 1 share of stock per warrant at a price of $25.

a. Calculate the exercise value of the firm's warrants if the common sells at each of the following prices: (1) $20, (2) $25, (3) $30, (4) $100. (*Hint:* A warrant's exercise value is the difference between the stock price and the purchase price specified by the warrant if the warrant were to be exercised.)
b. Assume the firm's stock now sells for $20 per share. The company wants to sell some 20-year, $1,000 par value bonds with interest paid annually. Each bond will have attached 50 warrants, each exercisable into 1 share of stock at an exercise price of $25. The firm's straight bonds yield 12%. Assume that each warrant will have a market value of $3 when the stock sells at $20. What coupon interest rate, and dollar coupon, must the company set on the bonds with warrants if they are to clear the market? (*Hint:* The convertible bond should have an initial price of $1,000.)

(20-4) Convertible Premiums

The Tsetsekos Company was planning to finance an expansion. The principal executives of the company all agreed that an industrial company such as theirs should finance growth by means of common stock rather than by debt. However, they felt that the current $42 per share price of the company's common stock did not reflect its true worth, so they decided to sell a convertible security. They considered a convertible debenture but feared the burden of fixed interest charges if the common stock did not rise enough in price to make conversion attractive. They decided on an issue of convertible preferred stock, which would pay a dividend of $2.10 per share.

a. The conversion ratio will be 1.0; that is, each share of convertible preferred can be converted into a single share of common. Therefore, the convertible's par value (and also the issue price) will be equal to the conversion price, which in turn will be determined as a premium (i.e., the percentage by which the

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

conversion price exceeds the stock price) over the current market price of the common stock. What will the conversion price be if it is set at a 10% premium? At a 30% premium?

b. Should the preferred stock include a call provision? Why or why not?

CHALLENGING PROBLEMS 5–7

(20-5) Convertible Bond Analysis

Fifteen years ago, Roop Industries sold $400 million of convertible bonds. The bonds had a 40-year maturity, a 5.75% coupon rate, and paid interest annually. They were sold at their $1,000 par value. The conversion price was set at $62.75, and the common stock price was $55 per share. The bonds were subordinated debentures and were given an A rating; straight nonconvertible debentures of the same quality yielded about 8.75% at the time Roop's bonds were issued.

a. Calculate the premium on the bonds—that is, the percentage excess of the conversion price over the stock price at the time of issue.
b. What is Roop's annual before-tax interest savings on the convertible issue versus a straight-debt issue?
c. At the time the bonds were issued, what was the value per bond of the conversion feature?
d. Suppose the price of Roop's common stock fell from $55 on the day the bonds were issued to $32.75 now, 15 years after the issue date (also assume the stock price never exceeded $62.75). Assume interest rates remained constant. What is the current price of the straight-bond portion of the convertible bond? What is the current value if a bondholder converts a bond? Do you think it is likely that the bonds will be converted? Why or why not?
e. The bonds originally sold for $1,000. If interest rates on A-rated bonds had remained constant at 8.75% and if the stock price had fallen to $32.75, then what do you think would have happened to the price of the convertible bonds? (Assume no change in the standard deviation of stock returns.)
f. Now suppose that the price of Roop's common stock had fallen from $55 on the day the bonds were issued to $32.75 at present, 15 years after the issue. Suppose also that the interest rate on similar straight debt had fallen from 8.75% to 5.75%. Under these conditions, what is the current price of the straight-bond portion of the convertible bond? What is the current value if a bondholder converts a bond? What do you think would have happened to the price of the bonds?

(20-6) Warrant/Convertible Decisions

The Howland Carpet Company has grown rapidly during the past 5 years. Recently, its commercial bank urged the company to consider increasing its permanent financing. Its bank loan under a line of credit has risen to $250,000, carrying an 8% interest rate. Howland has been 30 to 60 days late in paying trade creditors.

Discussions with an investment banker have resulted in the decision to raise $500,000 at this time. Investment bankers have assured the firm that the following alternatives are feasible (flotation costs will be ignored).

- *Alternative 1:* Sell common stock at $8.
- *Alternative 2:* Sell convertible bonds at an 8% coupon, convertible into 100 shares of common stock for each $1,000 bond (i.e., the conversion price is $10 per share).
- *Alternative 3:* Sell debentures at an 8% coupon, each $1,000 bond carrying 100 warrants to buy common stock at $10.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

John L. Howland, the president, owns 80% of the common stock and wishes to maintain control of the company. There are 100,000 shares outstanding. The following are extracts of Howland's latest financial statements:

Balance Sheet

		Current liabilities	$400,000
		Common stock, par $1	100,000
		Retained earnings	50,000
Total assets	$550,000	Total claims	$550,000

Income Statement

Sales	$1,100,000
All costs except interest	990,000
EBIT	$ 110,000
Interest	20,000
Pre-tax earnings	$ 90,000
Taxes (40%)	36,000
Net income	$ 54,000
Shares outstanding	100,000
Earnings per share	$ 0.54
Price/earnings ratio	15.83
Market price of stock	$ 8.55

a. Show the new balance sheet under each alternative. For Alternatives 2 and 3, show the balance sheet after conversion of the bonds or exercise of the warrants. Assume that half of the funds raised will be used to pay off the bank loan and half to increase total assets.
b. Show Mr. Howland's control position under each alternative, assuming that he does not purchase additional shares.
c. What is the effect on earnings per share of each alternative, assuming that profits before interest and taxes will be 20% of total assets?
d. What will be the debt ratio (TL/TA) under each alternative?
e. Which of the three alternatives would you recommend to Howland, and why?

(20-7) Convertible Bond Analysis

Niendorf Incorporated needs to raise $25 million to construct production facilities for a new type of USB memory device. The firm's straight nonconvertible debentures currently yield 9%. Its stock sells for $23 per share, has an expected constant growth rate of 6%, and has an expected dividend yield of 7%, for a total expected return on equity of 13%. Investment bankers have tentatively proposed that the firm raise the $25 million by issuing convertible debentures. These convertibles would have a $1,000 par value, carry a coupon rate of 8%, have a 20-year maturity, and be convertible into 35 shares of stock. Coupon payments would be made annually. The bonds would be noncallable for 5 years, after which they would be callable at a price of $1,075; this call price would decline by $5 per year in Year 6 and each year thereafter. For simplicity, assume that the bonds may be called or converted only at the end of a year, immediately after the coupon and dividend payments. Also assume that management would call eligible bonds if the conversion value exceeded 20% of par value (not 20% of call price).

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

a. At what year do you expect the bonds will be forced into conversion with a call? What is the bond's value in conversion when it is converted at this time? What is the cash flow to the bondholder when it is converted at this time? (*Hint:* The cash flow includes the conversion value and the coupon payment, because the conversion occurs immediately after the coupon is paid.)
b. What is the expected rate of return (i.e., the before-tax component cost) on the proposed convertible issue?

SPREADSHEET PROBLEM

(20-8) Build a Model: Convertible Bond Analysis

resource

Start with the partial model in the file ***Ch20 P08 Build a Model.xlsx*** on the textbook's Web site. Maggie's Magazines (MM) has straight nonconvertible bonds that currently yield 9%. MM's stock sells for $22 per share, has an expected constant growth rate of 6%, and has a dividend yield of 4%. MM plans on issuing convertible bonds that will have a $1,000 par value, a coupon rate of 8%, a 20-year maturity, and a conversion ratio of 32 (i.e., each bond could be convertible into 32 shares of stock). Coupon payments will be made annually. The bonds will be noncallable for 5 years, after which they will be callable at a price of $1,090; this call price would decline by $6 per year in Year 6 and each year thereafter. For simplicity, assume that the bonds may be called or converted only at the end of a year, immediately after the coupon and dividend payments. Management will call the bonds when their conversion value exceeds 25% of their par value (not their call price).

a. For each year, calculate: (1) the anticipated stock price, (2) the anticipated conversion value, (3) the anticipated straight-bond price, and (4) the cash flow to the investor assuming conversion occurs. At what year do you expect the bonds will be forced into conversion with a call? What is the bond's value in conversion when it is converted at this time? What is the cash flow to the bondholder when it is converted at this time? (*Hint:* The cash flow includes the conversion value and the coupon payment, because the conversion occurs immediately after the coupon is paid.)
b. What is the expected rate of return (i.e., the before-tax component cost) on the proposed convertible issue?
c. Assume that the convertible bondholders require a 9% rate of return. If the coupon rate remains unchanged, then what conversion ratio will give a bond price of $1,000?

MINI CASE

Paul Duncan, financial manager of EduSoft Inc., is facing a dilemma. The firm was founded 5 years ago to provide educational software for the rapidly expanding primary and secondary school markets. Although EduSoft has done well, the firm's founder believes an industry shakeout is imminent. To survive, EduSoft must grab market share now, and this will require a large infusion of new capital.

Because he expects earnings to continue rising sharply and looks for the stock price to follow suit, Mr. Duncan does not think it would be wise to issue new common stock at this time. On the other hand, interest rates are currently high by historical standards, and the firm's B rating means that interest payments on a new debt issue would be prohibitive. Thus, he has narrowed his choice of financing alternatives to: (1) preferred stock, (2) bonds with warrants, or (3) convertible bonds.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

As Duncan's assistant, you have been asked to help in the decision process by answering the following questions.

a. How does preferred stock differ from both common equity and debt? Is preferred stock more risky than common stock? What is floating rate preferred stock?
b. How can knowledge of call options help a financial manager to better understand warrants and convertibles?
c. Mr. Duncan has decided to eliminate preferred stock as one of the alternatives and focus on the others. EduSoft's investment banker estimates that EduSoft could issue a bond-with-warrants package consisting of a 20-year bond and 27 warrants. Each warrant would have a strike price of $25 and 10 years until expiration. It is estimated that each warrant, when detached and traded separately, would have a value of $5. The coupon on a similar bond but without warrants would be 10%.
   (1) What coupon rate should be set on the bond with warrants if the total package is to sell at par ($1,000)?
   (2) When would you expect the warrants to be exercised? What is a stepped-up exercise price?
   (3) Will the warrants bring in additional capital when exercised? If EduSoft issues 100,000 bond-with-warrant packages, how much cash will EduSoft receive when the warrants are exercised? How many shares of stock will be outstanding after the warrants are exercised? (EduSoft currently has 20 million shares outstanding.)
   (4) Because the presence of warrants results in a lower coupon rate on the accompanying debt issue, shouldn't all debt be issued with warrants? To answer this, estimate the anticipated stock price in 10 years when the warrants are expected to be exercised, and then estimate the return to the holders of the bond-with-warrants packages. Use the corporate valuation model to estimate the expected stock price in 10 years. Assume that EduSoft's current value of operations is $500 million and it is expected to grow at 8% per year.
   (5) How would you expect the cost of the bond with warrants to compare with the cost of straight debt? With the cost of common stock (which is 13.4%)?
   (6) If the corporate tax rate is 40%, what is the after-tax cost of the bond with warrants?
d. As an alternative to the bond with warrants, Mr. Duncan is considering convertible bonds. The firm's investment bankers estimate that EduSoft could sell a 20-year, 8.5% coupon (paid annually), callable convertible bond for its $1,000 par value, whereas a straight-debt issue would require a 10% coupon (paid annually). The convertibles would be call protected for 5 years, the call price would be $1,100, and the company would probably call the bonds as soon as possible after their conversion value exceeds $1,200. Note, though, that the call must occur on an issue-date anniversary. EduSoft's current stock price is $20, its last dividend was $1, and the dividend is expected to grow at a constant 8% rate. The convertible could be converted into 40 shares of EduSoft stock at the owner's option.
   (1) What conversion price is built into the bond?
   (2) What is the convertible's straight-debt value? What is the implied value of the convertibility feature?
   (3) What is the formula for the bond's expected conversion value in any year? What is its conversion value at Year 0? At Year 10?
   (4) What is meant by the "floor value" of a convertible? What is the convertible's expected floor value at Year 0? At Year 10?

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(5) Assume that EduSoft intends to force conversion by calling the bond as soon as possible after its conversion value exceeds 20% above its par value, or 1.2($1,000) = $1,200. When is the issue expected to be called? (*Hint:* Recall that the call must be made on an anniversary date of the issue.)
(6) What is the expected cost of capital for the convertible to EduSoft? Does this cost appear to be consistent with the riskiness of the issue?
(7) What is the after-tax cost of the convertible bond?

e. Mr. Duncan believes that the costs of both the bond with warrants and the convertible bond are close enough to call them even and that the costs are consistent with the risks involved. Thus, he will make his decision based on other factors. What are some of the factors that he should consider?
f. How do convertible bonds help reduce agency costs?

SELECTED ADDITIONAL CASES

The following cases from CengageCompose cover many of the concepts discussed in this chapter and are available at **http://compose.cengage.com.**

Klein-Brigham Series:
Case 27, "Virginia May Chocolate Company," which illustrates convertible bond valuation, and Case 98, "Levinger Organic Snack," which illustrates the use of convertibles and warrants.

CHAPTER 21

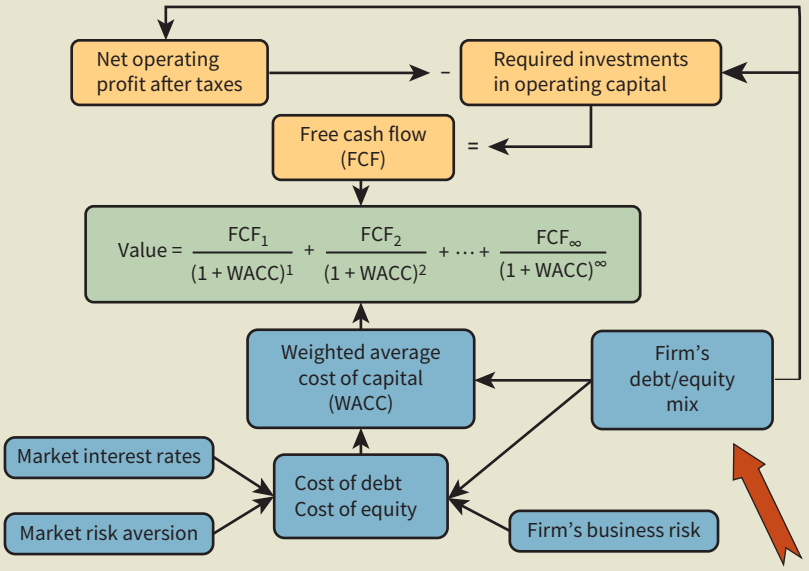
Dynamic Capital Structures and Corporate Valuation

Take a look at the two charts below. The first shows the ratio of total debt to book capital (as measured by book values from financial statements) for Hewlett-Packard (HPQ) and Procter & Gamble (PG). The second shows the ratio of total debt to total market capitalization (the sum of the market value of equity and the book value of debt).



Notice that Procter & Gamble has kept a very stable capital structure as measured by either ratio. In contrast, Hewlett-Packard's debt ratios have been volatile and have gone up and down. In theory, companies have target debt ratios. In practice, debt ratios are dynamic—some companies have a target but adjust to it slowly, other companies deliberately deviate from their target to take advantage of unexpected opportunities, and others change targets frequently. Think about the dynamic nature of Hewlett-Packard's capital structure as you read this chapter.

Corporate Valuation and Capital Structure Decisions

A firm's financing choices obviously have a direct effect on its weighted average cost of capital (WACC). Financing choices also have an indirect effect because they change the risk and required return of debt and equity. This chapter focuses on the debt–equity choice and its effect on value in a dynamic environment.

Chapter 15 described capital structure decisions, including the selection of an optimal capital structure. The analysis assumed a static capital structure in the sense that managers have a target and try to keep the actual capital structure equal to the target. However, capital structures often are dynamic. Some variation occurs without managerial actions, such as changes in the stock price due to overall market conditions. Some changes occur due to economies of scale with respect to raising capital—because of transaction costs, companies raise large amounts of capital less frequently instead of small amounts often. Other changes occur as companies deliberately deviate from their target to take advantage of unexpected opportunities, such as acquisition opportunities. Managers need to understand how a dynamic capital structure will affect firm value, which is the question we address in this chapter. We begin with a general framework for identifying the impact capital structure has on value.

21-1 The Adjusted Present Value (APV) Approach

Before addressing issues arising from dynamic capital structures, we need a framework for analyzing the impact of capital structure, beginning with a levered firm's value, V_L.

21-1a The Value of a Levered Firm (V_L)

The most general conceptual framework is to start with the value of an unlevered but otherwise identical firm, V_U, and adjust the unlevered value for any side effects

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. due to leverage. This is called the **adjusted present value approach (APV)** and is expressed as:

$$V_L = V_U + \text{Value of side effects} \quad \textbf{(21-1)}$$

The value of an unlevered firm is the present value of its free cash flows (FCF) discounted at the weighted average cost of capital (WACC). For an unlevered firm, the WACC is the unlevered cost of equity: $WACC = r_{sU}$. As we saw in the free cash flow corporate valuation model from Chapter 7, this present value is:

$$V_U = \sum_{t=1}^{\infty} \frac{FCF_t}{(1 + r_{sU})^t} \quad \textbf{(21-2)}$$

As shown in Chapter 7, if FCF grows at a constant rate of g_L, then Equation (21-2) can be simplified:

$$V_U = \sum_{t=1}^{\infty} \frac{FCF_0(1 + g_L)^t}{(1 + r_{sU})^t} = \frac{FCF_1}{r_{sU} - g_L} \quad \textbf{(21-3)}$$

In Chapter 15, we discussed some of the side effects of leverage, including benefits due to deductibility of interest expenses and costs due to financial distress. We will focus on the tax benefits now and address the costs of financial distress later.

The tax benefits due to leverage are the annual **tax savings due to interest (TS_t)**, which are the annual reductions in taxes resulting from the deductibility of interest expenses. If r_d is the interest rate on debt, D_t is the amount of debt (which we assume to be constant during the year), and T is the tax rate, then the reduction in taxes in a given year due to deducting interest expense is:

$$TS_t = (\text{Interest expense})(T) = r_d D_t T \quad \textbf{(21-4)}$$

Each year a levered company can deduct its interest expenses, so the value of the levered firm is equal to the value of the unlevered firm plus the gain from leverage, which is the present value of the interest tax savings, also known as the **interest tax shield ($V_{\text{Tax shield}}$)**:

$$V_L = V_U + V_{\text{Tax shield}} \quad \textbf{(21-1a)}$$

The value of the tax shield is the present value of all of the interest tax savings (TS), discounted at the appropriate rate, r_{TS}:

$$V_{\text{Tax shield}} = \sum_{t=1}^{\infty} \frac{TS_t}{(1 + r_{TS})^t} = \sum_{t=1}^{\infty} \frac{r_d TD_t}{(1 + r_{TS})^t} \quad \textbf{(21-5)}$$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

If free cash flows grow at a constant rate and the proportions of debt and equity in the capital structure remain constant, then the annual tax savings grow at a constant rate. Using the constant growth model, the present value of these growing tax savings is:

$$V_{\text{Tax shield}} = \sum_{t=1}^{\infty} \frac{r_d T D_0 (1+g_L)^t}{(1+r_{TS})^t} = \frac{r_d T D_0 (1+g_L)}{r_{TS} - g_L} \quad (21\text{-}6)$$

Substituting Equation 21-6 into Equation 21-1a yields a valuation expression that separately identifies the impact of leverage and growth on value:

$$V_L = V_U + \left(\frac{r_d}{r_{TS} - g_L}\right)(T)(D_0)(1+g_L) \quad (21\text{-}7)$$

Equation 21-7 is a very general model of the adjusted present value approach. We will examine some specific applications of this general approach later, but now we address the impact of leverage on the cost of equity.

21-1b The Levered Cost of Equity (r_{sL})

With considerable algebra, the levered cost of equity (r_{sL}) can be expressed in terms of: (1) the unlevered cost of equity, (2) the capital structure weights (w_d is the percentage of the firm financed with debt and w_s is the percentage financed with common stock), (3) the cost of debt (r_d), and (4) the discount rate for the tax shield:

$$r_{sL} = r_{sU} + (r_{sU} - r_d)\frac{w_d}{w_s} - (r_{sU} - r_{TS})\left[\frac{r_d T}{r_{TS} - g_L}\right]\frac{w_d}{w_s} \quad (21\text{-}8)$$

The ratio of w_d/w_s in Equation 21-8 is also equal to the ratio D/S, where S is the value of the stock. For some problems it is easier to use the ratio of D/S if you have already calculated D and S; in other problems, you might have a target capital structure, so it is easier to use the ratio w_d/w_s. Depending on the situation, we use the form of the leverage ratio (D/S or w_d/w_s) that reduces the number of calculations and saves the most time, so be aware of this as you read the chapter and work problems.

21-1c The Levered Beta (b)

With a little more algebra, we can express a company's beta as a function of the unlevered beta of stock, b_U, the beta of the debt, b_d, and the beta of the tax shield, b_{TS}; the betas of the debt and the tax shield reflect the systematic risk of debt and the tax shield. The levered beta of a company is:

$$b = b_U + (b_U - b_d)\frac{w_d}{w_s} - (b_U - b_{TS})\left[\frac{r_d T}{r_{TS} - g_L}\right]\frac{w_d}{w_s} \quad (21\text{-}9)$$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Observe that Equation 21-9 includes the term b_d. If corporate debt is not riskless, then its beta, b_d, may not be zero. If we assume that bonds lie on the Security Market Line, then a bond's required return, r_d, can be expressed as $r_d = r_{RF} + b_d RP_M$. Solving for b_d gives $b_d = (r_d - r_{RF})/RP_M$.

21-1d The Tax Shield Discount Rate (r_{TS})

Notice that the value of a levered firm (Equation 21-7), the levered cost of equity (21-8), and the levered beta (21-9) each depends on the assumed rate for discounting the tax shield, r_{TS}. Although r_{TS} cannot be directly observed, we can put some bounds on it, as we show next.

If the company will always get to deduct interest expenses, then the tax shield has no risk and should be discounted at the risk-free rate. However, corporate debt is not riskless—firms do occasionally default on their loans if cash flows from operations are so low that the firm's value is less than the debt's value. Even if a company doesn't default on its debt, a company might not be able to use tax savings from interest deductions in the current year if it has a pre-tax operating loss. Therefore, the future tax savings are not risk free and hence should be discounted using a higher rate than the risk-free rate.[1]

How much higher should the discount rate be? The risk that the company will not be able to use future interest rate deductions stems from the risk of its pre-tax operating profit. This suggests that the unlevered cost of equity, which reflects the risk of operations, should be an upper limit for the required return on the tax shield.

The following sections describe some special cases of the adjusted present value model that correspond to particular values of r_{TS}.

SELF-TEST

What does the term "value of an unlevered firm" mean?

What is the tax shield of interest?

How does the value of a levered firm compare to the value of an unlevered firm that is otherwise identical?

21-2 The Modigliani and Miller Models

Recall from Chapter 15 that Modigliani and Miller (MM) developed a model of capital structure based on the assumption of zero growth ($g_L = 0$) and no risk of bankruptcy ($b_d = 0$). In addition, they assumed that the appropriate discount rate for

[1]The discount rate for the tax shield, r_{TS}, must also be greater than the growth rate, g_L. To see this, look at the first row in Equation 21-6. If r_{TS} is greater than g_L, then the ratio of $(1 + r_{TS})/(1 + g_L)$ will be greater than 1, causing each term in the infinite series to be greater than the initial tax shield of $r_d(T)(D_0)$. We know that the value of the tax shield can't be infinite, so r_{TS} must be greater than g_L.

If g_L is high and r_{TS} is barely greater than g_L, then the third term in Equation 21-8 can be larger than the second term, causing the levered cost of equity to be less than the unlevered cost of equity! The combination of a high g_L and relatively low r_{TS} would also cause the value of a levered firm in Equation 21-7 to be very large. Consequently, high-growth firms would choose high levels of leverage, but this is inconsistent with low levels of leverage actually chosen by high-growth firms. Therefore, r_{TS} probably is much larger than g_L. In fact, the levered cost of equity cannot be lower than the unlevered cost of equity if $r_{TS} = r_{sU}$. For a more detailed discussion, see Michael C. Ehrhardt and Phillip R. Daves, "Corporate Valuation: The Combined Impact of Growth and the Tax Shield of Debt on the Cost of Capital and Systematic Risk," *Journal of Applied Finance,* Fall/Winter 2002, pp. 31–38.

the tax shield is $r_{TS} = r_d$. They made this assumption because the annual tax savings are proportional to the annual debt, which implies that the tax savings have the same risk as debt. MM examined two situations, one with no taxes and one with corporate taxes.

21-2a Modigliani and Miller: No Taxes

In addition to the previous assumptions (including zero growth), MM's first model assumed no taxes. Substituting $g_L = 0$ and $T = 0$ into Equations 21-7 and 21-8 provides the MM results for zero taxes from Chapter 15:

$$V_L = V_U \quad \textbf{(21-10)}$$

and

$$r_{sL} = r_{sU} + (r_{sU} - r_d)(w_d/w_s) \quad \textbf{(21-11)}$$

21-2b Modigliani and Miller: Corporate Taxes

Substituting $g_L = 0$ and $r_{TS} = r_d$ into Equations 21-7 and 21-8 but allowing T to be nonzero provides the MM results when corporate taxes are considered:

$$V_L = V_U + TD \quad \textbf{(21-12)}$$

and

$$r_{sL} = r_{sU} + (r_{sU} - r_d)(1 - T)(w_d/w_s) \quad \textbf{(21-13)}$$

Substituting $g = 0$, $b_d = 0$, and $r_{TS} = r_d$ into Equation 21-9 (and allowing T to be nonzero) provides the Hamada equation from Chapter 15:

$$b = b_U[1 + (1 - T)(w_d/w_s)] \quad \textbf{(21-14)}$$

Therefore, the MM models are special cases of the more general adjusted present value approach. The following section provides another special case that is widely used, the compressed APV model.

SELF-TEST

Using the adjusted present value model, under what assumptions are the MM (no taxes) results correct?

Using the adjusted present value model, under what assumptions are the MM (with corporate taxes) results correct?

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

21-3 The Compressed Adjusted Present Value (CAPV) Model

In contrast to the MM models, the **compressed adjusted present value (CAPV) model** allows nonzero growth and risky debt with a nonzero debt beta.[2] It also differs from the MM models in its assumption regarding the appropriate discount rate for the tax shield. In particular, it assumes that $r_{TS} = r_{sU}$.

Substituting $r_{TS} = r_{sU}$ into the general valuation model in Equation 21-7, we get:

$$V_L = V_U + \left(\frac{r_d T D_1}{r_{sU} - g_L}\right) \quad \textbf{(21-15)}$$

Notice that the gain from leverage (the second term in Equation 21-15) can be larger or smaller than the gain from leverage in the MM model with taxes, depending on the fraction $r_d/(r_{sU} - g_L)$. If the cost of debt is low relative to the spread between the unlevered cost of equity and the growth rate, then a growing tax shield is very valuable. On the other hand, if growth is very low (or zero), then fraction $r_d/(r_{sU} - g_L)$ is less than 1, which means that the gain from leverage is bigger in the MM model than in the APV model. This makes sense, because the MM model discounts the tax savings at the relatively low cost of debt, r_d, while the CAPV model discounts the tax savings at the relatively high unlevered cost of equity, r_{sU}.

Substituting $r_{TS} = r_{sU}$ into Equation 21-8 shows that the levered cost of equity is:

$$r_{sL} = r_{sU} + (r_{sU} - r_d)(w_d/w_s) \quad \textbf{(21-16)}$$

Although the derivation of Equation 21-16 reflects corporate taxes and growth, neither of these expressions includes the corporate tax rate or the growth rate. This means that the expression for the levered required rate of return, Equation 21-16, is exactly the same as MM's expression for the levered required rate of return *without taxes*, Equation 21-11. The reason the tax rate and the growth rate drop out of these two expressions is that the growing tax shield is discounted at the unlevered cost of equity, r_{sU}, not at the cost of debt as in the MM model. The tax rate drops out because no matter how high the level of T, the total risk of the firm will not be changed—the unlevered cash flows and the tax shield are discounted at the same rate. The growth rate drops out for the same reason—an increasing debt level will not change the risk of the entire firm no matter what rate of growth prevails.

Substituting $r_{TS} = r_{sU}$ and $b_{TS} = b_U$ into Equation 21-9 shows the levered beta:

$$b = b_U + (b_U - b_d)(w_d/w_s) \quad \textbf{(21-17)}$$

[2]It is called the *compressed* APV because it is not necessary to separately discount FCF and the interest tax shield when calculating the value of the levered firm because each is discounted at the unlevered cost of equity. However, we usually discount separately the forecasted FCF and tax shields so that we can more easily identify the impact on value due to operations versus leverage.

For more on the compressed APV, see Steven N. Kaplan and Richard S. Ruback, "The Valuation of Cash Flow Forecasts: An Empirical Analysis," *Journal of Finance*, September 1995, pp. 1059–1093. For evidence showing the effectiveness of the adjusted present value approach, see S. N. Kaplan and R. S. Ruback, "The Market Pricing of Cash Flow Forecasts: Discounted Cash Flow vs. the Method of 'Comparables,'" *Journal of Applied Corporate Finance*, Winter 1996, pp. 45–60.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

If the systematic risk of debt is small enough to neglect, then the relationship between the levered beta and the unlevered beta is:

$$b = b_U[1 + (w_d/w_s)] \quad \textbf{(21-17a)}$$

This expression for the levered beta is exactly the same as Hamada's formula in Equation 21-14, but *without taxes*.

We will use the compressed APV model to determine the value of a company whose capital structure is changing during the forecast period, but we begin with the valuation of a company with a stable capital structure.

SELF-TEST

Using the adjusted present value model, under what assumptions are the compressed APV results correct?

21-4 Multistage Valuation When the Capital Structure Is Stable

In this section we briefly review the free cash flow (FCF) valuation model from Chapter 7, we introduce the free cash flow to equity (FCFE) model, and we modify the compressed APV model for application to a firm with nonconstant FCF growth in the forecast period (but constant FCF growth after the forecast horizon). To better focus on the impact of leverage due to debt, we assume that the models are being applied to a firm without any preferred stock or nonoperating assets.

21-4a A Brief Review of the Multistage FCF Corporate Valuation Model

Recall the free cash flow valuation model from Chapter 7, in which the value of operations (V_{op}) is equal to the present value of expected future free cash flows (FCF) discounted at the weighted average cost of capital (WACC). FCF growth can be nonconstant *during* the forecast period but the rate of growth (g_L) must become constant *by the end* of the forecast period (Period N), which is called the horizon. The horizon value ($HV_{FCF,N}$) is the present value of all FCF beyond the horizon, discounted back to the horizon date. The horizon value of the FCF at time N ($HV_{FCF,N}$) is:

$$HV_{FCF,N} = \frac{FCF_N(1 + g_L)}{WACC - g_L} \quad \textbf{(21-18)}$$

The present value of all FCF is the value of operations (V_{FCF}):[3]

$$V_{FCF} = \sum_{t=1}^{N} \frac{FCF_t}{(1 + WACC)^t} + \frac{HV_{FCF,N}}{(1 + WACC)^N} \quad \textbf{(21-19)}$$

[3]We denoted the value of operations as V_{op} in Chapters 7 and 12, but we use V_{FCF} here to distinguish it from other valuation approaches that we discuss in this chapter.

Because we assume that there is no preferred stock and that there are no nonoperating assets, the total value of equity is found by subtracting the value of all debt from the total value. The price per share is found by dividing the total value of equity by the number of shares.

21-4b The Multistage Free Cash Flow to Equity (FCFE) Approach

Free cash flow is the cash flow available for distribution to *all* investors. In contrast, **free cash flow to equity (FCFE)** is the cash flow available for distribution to *common shareholders*. Because FCFE is available for distribution only to shareholders, it should be discounted at the levered cost of equity, r_{sL}. Therefore, the **free cash flow to equity approach**, also called the **equity residual model**, discounts the projected FCFE at the cost of equity to determine the value of the equity.

Because FCFE is the cash flow available for distribution to shareholders, it may be used to pay common dividends, repurchase stock, purchase financial assets, or some combination of these uses. In other words, the uses of FCFE include all those of FCF except for distributions to debtholders. Therefore, one way to calculate FCFE is to start with FCF and reduce it by the net after-tax distributions to debtholders:

$$\begin{aligned} \text{FCFE} &= \begin{matrix}\text{Free}\\ \text{cash flow}\end{matrix} - \begin{matrix}\text{After-tax}\\ \text{interest expense}\end{matrix} - \begin{matrix}\text{Principal}\\ \text{payments}\end{matrix} + \begin{matrix}\text{Newly issued}\\ \text{debt}\end{matrix} \\ &= \begin{matrix}\text{Free}\\ \text{cash flow}\end{matrix} - \begin{matrix}\text{Interest}\\ \text{expense}\end{matrix} + \begin{matrix}\text{Interest}\\ \text{tax shield}\end{matrix} + \begin{matrix}\text{Net change}\\ \text{in debt}\end{matrix} \end{aligned} \tag{21-20}$$

Alternatively, the FCFE can be calculated as:

$$\text{FCFE} = \text{Net income} - \begin{matrix}\text{Investment in total}\\ \text{net operating capital}\end{matrix} + \begin{matrix}\text{Net change}\\ \text{in debt}\end{matrix} \tag{21-20a}$$

Given projections of FCFE, the value of a firm's equity, V_{FCFE}, is:

$$V_{FCFE} = \sum_{t=1}^{\infty} \frac{FCFE_t}{(1 + r_{sL})^t} \tag{21-21}$$

If we assume constant growth beyond the horizon, then the horizon value of the equity, $HV_{FCFE,N}$, is:

$$HV_{FCFE,N} = \frac{FCFE_{N+1}}{r_{sL} - g_L} = \frac{FCFE_N(1 + g_L)}{r_{sL} - g_L} \tag{21-22}$$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The value of equity is the present value of the horizon value and the FCFE during the forecast period:

$$V_{FCFE} = \sum_{t=1}^{N} \frac{FCFE_t}{(1 + r_{sL})^t} + \frac{HV_{FCFE,N}}{(1 + r_{sL})^N} \quad (21\text{-}23)$$

To get a per share price, simply divide the value of equity by the shares outstanding.[4] Like the FCF corporate valuation model, the FCFE model can be applied only when the capital structure is constant.

21-4c The Multistage Compressed APV Approach

To estimate the unlevered value of operations, V_U, we need the projected free cash flows and the unlevered cost of equity, r_{sU}. It is straightforward to estimate the projected free cash flows, as shown in Chapters 7 and 12. It can be a bit more complicated to estimate the unlevered cost of equity. If the company being analyzed currently has no debt, then its current cost of equity *is* the unlevered cost of equity. If the company already has some debt, then we need to unlever its current cost of equity. The Hamada equation is based on the MM model with corporate taxes, which discounts the tax savings at the cost of debt and which assumes zero growth, making the Hamada equation inappropriate for applications of the compressed APV model.

Instead, we use Equation 21-16 to estimate the unlevered cost of equity if we already know the levered cost of equity. If instead we already know the beta, we find the unlevered beta using Equation 21-17 (or 21-18 if we ignore the debt beta) and use the Capital Asset Pricing Model (CAPM) to estimate the unlevered cost of equity. Given the estimated FCF and unlevered cost of equity, the unlevered value of operations is the present value of the firm's free cash flows discounted at the unlevered cost of equity:

$$V_U = \sum_{t=1}^{\infty} \frac{FCF_t}{(1 + r_{sU})^t} \quad (21\text{-}24)$$

If the FCFs grow at a nonconstant rate during the forecast period but grow at a constant rate after the forecast horizon, then we first find the horizon value of the unlevered firm ($HV_{U,N}$):

$$HV_{U,N} = \frac{FCF_N(1 + g_L)}{r_{s,U} - g_L} \quad (21\text{-}25)$$

[4]The FCFE model is similar to the dividend growth model in that cash flows are discounted at the cost of equity. The models are equivalent if there is no preferred stock and there are no nonoperating assets.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The total value of the unlevered firm is:

$$V_U = \sum_{t=1}^{N} \frac{FCF_t}{(1 + r_{s,U})^t} + \frac{HV_{U,N}}{(1 + r_{s,U})^N} \quad \textbf{(21-26)}$$

As described earlier, the compressed APV discounts the tax savings at the unlevered cost of equity, so the value of the tax shield is:

$$V_{\text{Tax shield}} = \sum_{t=1}^{N} \frac{TS_t}{(1 + r_{sU})^t} \quad \textbf{(21-27)}$$

If the annual tax shields grow at a nonconstant rate during the forecast period but grow at a constant rate after the forecast horizon, then we first find the horizon value of the tax shields ($HV_{TS,N}$):

$$HV_{TS,N} = \frac{TS_N(1 + g_L)}{r_{s,U} - g_L} \quad \textbf{(21-28)}$$

The total value of the shield is:

$$V_{\text{Tax shield}} = \sum_{t=1}^{N} \frac{TS_t}{(1 + r_{s,U})^t} + \frac{HV_{TS,N}}{(1 + r_{s,U})^N} \quad \textbf{(21-29)}$$

The total value of operations is the sum of the unlevered value and the value of the tax shield. Because we assume that there is no preferred stock and that there are no nonoperating assets, the total value of equity is found by subtracting the value of all debt from the total value of operations. The price per share is found by dividing the total value of equity by the number of shares.

The compressed APV model gets its name from the fact that the annual FCFs and tax savings can be added together before conducting any calculations; in other words, the annual FCFs and tax savings can be "compressed" into a single stream of cash flows. When discounted at the unlevered cost of equity, the present value of this single stream of cash flows is the value of operations.

Table 21-1 summarizes the three cash flow valuation methods and their assumptions.

Notice that that all three models assume that growth in FCFs must be constant after the horizon date and that the capital structure must be constant after the horizon date. However, only the compressed APV approach is valid if the capital structure is nonconstant during the forecast period. The next section illustrates all three models for the situation in which the capital structure is constant, followed by an example of the compressed APV approach when the capital structure changes during the forecast period.

TABLE 21-1
Summary of Cash Flow Approaches

	Approach		
	Corporate FCF Valuation Model	**Free Cash Flow to Equity Model**	**APV Model**
Cash flow Definition	FCF = NOPAT − Net investment in operating capital	FCFE = FCF − Interest expense + Interest tax shield + Net change in debt	(1) FCF and (2) Interest tax savings
Discount rate	WACC	r_{sL} = Cost of equity	r_{sU} = Unlevered cost of equity
Result of present value calculation	Value of operations	Value of equity	(1) Value of unlevered operations and (2) Value of the tax shield; together, these are the value of operations
How to get equity value	Value of operations − Value of debt	Value of equity as calculated above.	Value of operations − Value of debt
Assumption about capital structure during forecast period	Capital structure is stable	Capital structure is stable	None
Requirement for analyst to project interest expense	No interest expense projections needed	Projected interest expense must be based on the assumed capital structure	Interest expense projections are unconstrained
Assumption at horizon	FCF grows at constant rate g_L	FCFE grows at constant rate g_L	FCF and interest tax savings grow at constant rate g_L (because capital structure is stable after horizon)

Note: To better focus on the impact of leverage due to debt, the definitions here assume that there is no preferred stock and that there are no nonoperating assets.

SELF-TEST

What cash flows are discounted in the FCFE model, and what is the discount rate?

How do the FCFE, corporate FCF valuation, and compressed APV models differ? How are they similar?

21-5 Illustration of the Three Valuation Approaches for a Constant Capital Structure

To illustrate the three valuation approaches, consider Tutwiler Controls, a small technology company specializing in voice-activated commands. Tutwiler currently has a $62.5 million market value of equity and $27 million in debt, for a total market value of $89.5 million. Thus, Tutwiler's current capital structure consists of 30.17% debt: $\$27/(\$62.5 + \$27) = 30.17\%$. Tutwiler intends to maintain this capital structure throughout the projection period and thereafter. Tutwiler is a publicly traded company, and its market-determined beta is 1.2. Given a risk-free rate of 7% and a 5% market risk premium, the CAPM produces a required rate of return on equity, r_{sL}, of:

$$\begin{aligned} r_{sL} &= r_{RF} + b(RP_M) \\ &= 7\% + 1.2(5\%) = 13\% \end{aligned}$$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Tutwiler's cost of debt is 9% and its federal-plus-state tax rate is 40%. Its WACC is:

$$\begin{aligned} \text{WACC} &= w_d(1 - T)r_d + w_s r_{sL} \\ &= 0.3017(1 - 0.40)(9\%) + 0.6983(13\%) \\ &= 10.707\% \end{aligned}$$

What is Tutwiler's intrinsic value? Is the market overvaluing or undervaluing Tutwiler? To determine these answers, we apply the FCF corporate valuation model, the compressed APV model, and the FCFE model in the following sections. As you will see, all three models produce an identical intrinsic value of equity, but keep in mind this is only because the capital structure is constant. If the capital structure were to change during the projection period (before becoming stable after the forecast horizon), then only the compressed APV model could be used. Section 21-6 illustrates application of the compressed APV in the case of a nonconstant capital structure.

21-5a Cash Flow Projections

resource

*See **Ch21 Tool Kit.xlsx** for details.*

We discussed financial projections in Chapter 12, but here we simply use the projections; see ***Web Extension 21A*** for a discussion that focuses on projecting financial statements that maintain a constant capital structure.

Table 21-2 shows the projections for Tutwiler. FCF is assumed to grow at a 5.5% rate after the forecast period.

Panel A of Table 21-2 shows selected items from the projected financial statements. Panel B shows the calculations for free cash flow, which are used in the corporate FCF valuation model. Row 9 shows net operating profit after taxes (NOPAT), which is equal to EBIT(1 − T). Row 10 shows the net investment in operating capital, which is the annual change in the total net operating capital in Row 8. Free cash flow, shown in Row 11, is equal to NOPAT less the net investment in operating capital.

Panel C shows the cash flows that will be used in the APV model. In particular, Row 13 shows the annual tax shield, which is equal to the interest expense multiplied by the tax rate. Panel D, using Equation 21-20, provides the calculations for FCFE.

Following are valuations of Tutwiler using all three methods, beginning with the FCF corporate valuation model.

21-5b Valuation Using the Corporate FCF Valuation Model

resource

*See **Ch21 Tool Kit.xlsx** on the textbook's Web site for all calculations. Note that rounded intermediate values are shown in the text, but all calculations are performed in* Excel *using nonrounded values.*

Tutwiler's free cash flows are shown in Row 11 of Table 21-2. The horizon value of Tutwiler's free cash flows as of 2021 can be calculated using the constant growth formula shown in Equation 21-18:

$$\begin{aligned} HV_{FCF,2021} &= \frac{FCF_{2022}}{WACC - g_L} = \frac{FCF_{2021}(1 + g_L)}{WACC - g_L} \\ &= \frac{\$6.200(1.055)}{0.107073 - 0.055} = \$125.61 \text{ million} \end{aligned}$$

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

TABLE 21-2
Projections for Tutwiler (Millions of Dollars)

	1/1/17	12/31/17	12/31/18	12/31/19	12/31/20	12/31/21
Panel A: Selected Items from Projected Financial Statements						
1. Net sales		$102.0	$123.5	$150.5	$172.5	$190.0
2. Cost of goods sold		80.0	94.0	113.0	129.0	142.0
3. Selling and administrative expenses		10.0	12.0	13.0	15.0	16.0
4. Depreciation		8.0	8.0	9.0	9.0	10.0
5. EBIT		$4.0	$9.5	$15.5	$19.5	$22.0
6. Interest expense[a]		2.4	2.7	2.9	3.1	3.2
7. Debt[b]	$27.5	29.8	32.1	34.1	35.9	37.9
8. Total net operating capital	116.0	118.0	121.0	125.2	131.0	138.0
Panel B: Corporate Valuation Model Cash Flows						
9. NOPAT = EBIT(1 − T)[c]		$2.4	$5.7	$9.3	$11.7	$13.2
10. Less net investment in operating capital		2.0	3.0	4.2	5.8	7.0
11. Free cash flow		$0.4	$2.7	$5.1	$5.9	$6.2
Panel C: APV Model Cash Flows						
12. Free cash flow		$0.4	$2.7	$5.1	$5.9	$6.2
13. Interest tax saving = Interest(T)		$1.0	$1.1	$1.2	$1.2	$1.3
Panel D: FCFE Model Cash Flows						
14. Free cash flow		$0.4	$2.7	$5.1	$5.9	$6.2
15. Less A-T interest = Interest(1 − T)		2.4	2.7	2.9	3.1	3.2
16. Plus change in debt		2.8	2.4	1.9	1.9	2.0
17. FCFE		$1.7	$3.5	$5.3	$5.9	$6.2

Source: See the file ***Ch21 Tool Kit.xlsx***. Numbers are reported as rounded values for clarity, but are calculated using *Excel*'s full precision. Thus, intermediate calculations using the figure's rounded values will be inexact.

Notes:

[a] Interest payments are based on Tutwiler's existing debt and additional debt required to finance annual growth.

[b] Debt is existing debt plus additional debt required to maintain a constant capital structure.

[c] The tax rate is 40%.

As shown in Equation 21-19, the value of operations is the present value of the free cash flows in the forecast period plus the present value of the horizon value. For January 1, 2017, the value is:

$$\begin{aligned} V_{FCF} &= \frac{\$0.40}{(1+0.107073)^1} + \frac{\$2.70}{(1+0.107073)^2} + \frac{\$5.10}{(1+0.107073)^3} \\ &\quad + \frac{\$5.90}{(1+0.107073)^4} + \frac{\$6.20 + \$125.61}{(1+0.107073)^5} \\ &= \$89.5 \end{aligned}$$

There are no nonoperating assets, so the intrinsic value of Tutwiler's equity is equal to the value of operations less the value of debt:

$$\text{Intrinsic S} = \$89.5 - \$27 = \$62.5 \text{ million}$$

The actual market value of equity is $62.50 million, so the market value and intrinsic value are quite close.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

21-5c Valuation Using the APV Approach

The APV approach requires an estimate of Tutwiler's unlevered cost of equity. As shown previously in Equation 21-16, the levered cost of equity is:

$$r_{sL} = r_{sU} + (r_{sU} - r_d)(w_d/w_s) \quad \textbf{(21-16)}$$

Using Tutwiler's capital structure, levered cost of equity, and cost of debt, Equation 21-16 can be rearranged to estimate the unlevered cost of equity:

$$r_{sU} = w_s r_{sL} + w_d r_d \quad \textbf{(21-16a)}$$

$$= 0.6983(13\%) + 0.3017(9\%)$$
$$= 11.793\%$$

In other words, if Tutwiler had no debt, its cost of equity would be 11.793%.[5]

Instead of directly estimating the unlevered cost of equity, we can estimate the unlevered beta, b_U, and then calculate the unlevered cost of equity. As shown previously in Equation 21-17, the unlevered beta is:

$$b = b_U + (b_U - b_d)(w_U/w_s) \quad \textbf{(21-17)}$$

where b_d is the beta of the debt.

Notice that this is different from the Hamada formula in Chapter 15. First, the Hamada formula assumes zero growth, but Equation 21-17 incorporates growth. Second, the Hamada formula assumes riskless debt. But if the CAPM is used to estimate the risk of equity, then the CAPM must be used to estimate the risk of debt; otherwise, we would be comparing apples to oranges.

To estimate the beta on debt due to systematic risk, we can start with the observed cost of debt and solve the CAPM for the implied beta on debt:

$$b_d = (r_d - r_{RF})/RP_M$$
$$= (0.09 - 0.07)/0.05$$
$$= 0.4$$

Rearranging Equation 21-17, Tutwiler's unlevered beta is:

$$b_U = [b + b_d(w_d/w_s)]/[1 + (w_d/w_s)]$$
$$= [1.2 + 0.4(0.3017/0.6983)]/[1 + (0.3017/0.6983)]$$
$$= 0.9586$$

Using the CAPM, the unlevered cost of equity is:

$$r_{sU} = r_{RF} + b_U(RP_M)$$
$$= 7\% + 0.9586(5\%) = 11.793\%$$

[5]Notice that we do not use the Hamada equation to lever or unlever beta; nor do we use the MM model with taxes to lever or unlever the required return on equity. These models assume zero growth and they assume that the discount rate for the tax shield is the cost of debt, but neither assumption is true for this example. Instead, we use Equations 21-16 and 21-17, which assume that the growing debt tax shield is discounted at the unlevered cost of equity.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

This is exactly the same value previously estimated. Because this alternative approach requires that we assume the CAPM is the correct model, and because it takes extra steps, we usually use the first method shown in Equations 21-16 and 21-16a.

The horizon value of Tutwiler's unlevered cash flows ($HV_{U,2021}$) and tax shield ($HV_{TS,2021}$) can be calculated using the constant growth formula with the unlevered cost of equity as the discount rate, as shown in Equations 21-25 and 21-28:[6]

$$HV_{U,2021} = \frac{FCF_{2022}}{r_{sU} - g_L} = \frac{FCF_{2021}(1 + g_L)}{r_{sU} - g_L} = \frac{\$6.2000(1.055)}{0.11793 - 0.055} = \$103.9 \text{ million}$$

$$HV_{TS,2021} = \frac{TS_{2022}}{r_{sU} - g_L} = \frac{TS_{2021}(1 + g_L)}{r_{sU} - g_L} = \frac{\$1.2931(1.055)}{0.11793 - 0.055} = \$21.7 \text{ million}$$

The sum of the two horizon values is $\$103.9 + \$21.7 = \$125.6$ million. This is the total horizon value of operations, which is the same as the horizon value calculation we obtained previously using the FCF corporate valuation model.

Row 11 in Table 21-2 shows the projected free cash flows. Using Equation 21-26, the unlevered value of operations is:

$$\begin{aligned} V_U &= \frac{\$0.40}{(1 + 0.11793)^1} + \frac{\$2.70}{(1 + 0.11793)^2} + \frac{\$5.10}{(1 + 0.11793)^3} \\ &\quad + \frac{\$5.90}{(1 + 0.11793)^4} + \frac{\$6.20 + \$103.9}{(1 + 0.11793)^5} \\ &= \$73.0 \text{ million} \end{aligned}$$

This shows that Tutwiler's operations would be worth $73.0 million if it had no debt.

Row 13 shows the yearly interest tax savings. Using Equation 21-29, the value of the tax shield is:

$$\begin{aligned} V_{\text{Tax shield}} &= \frac{\$0.97}{(1 + 0.11793)^1} + \frac{\$1.07}{(1 + 0.11793)^2} + \frac{\$1.16}{(1 + 0.11793)^3} \\ &\quad + \frac{\$1.23}{(1 + 0.11793)^4} + \frac{\$1.29 + \$21.68}{(1 + 0.11793)^5} \\ &= \$16.5 \text{ million} \end{aligned}$$

resource

*See **Ch21 Tool Kit.xlsx** on the textbook's Web site for all calculations. Note that rounded intermediate values are shown in the text, but all calculations are performed in Excel using nonrounded values.*

Thus, Tutwiler's operations would be worth only $73.0 million if it had no debt, but its capital structure contributes $16.5 million in value due to the tax deductibility of its interest payments. Because Tutwiler has no nonoperating assets, the total value of the firm is the sum of the unlevered value of operations, $73.0 million, and the value of the tax shield, $16.5 million, for a total of $89.5 million. The value of the equity is this total value less Tutwiler's outstanding debt of $27 million: $\$89.5 - \$27 = \$62.5$ million. Note that this is the same value we obtained using the corporate valuation model.

Now suppose we add together the annual FCFs and interest tax savings, creating a single stream of total annual cash flows ($TotalCF_t$):

	2017	2018	2019	2020	2021
Free cash flow =	$0.4000	$2.7000	$5.1000	$5.9000	$6.2000
Interest tax saving = Interest(T) =	$0.9720	$1.0719	$1.1574	$1.2259	$1.2931
Total annual cash flow	$1.3720	$3.7719	$6.2574	$7.1259	$7.4931

[6]Note that we report two decimal places for the 2021 tax shield even though Table 21-2 reports only one decimal place. All calculations are performed using the full nonrounded values in the *Excel* file ***Ch21 Tool Kit.xlsx***.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Using the unlevered cost of equity, the horizon value of the total annual cash flows ($HV_{TotalCF}$) is:

$$HV_{TotalCF,2021} = \frac{TotalCF_{2021}(1+g_L)}{r_{sU}-g_L} = \frac{\$7.493(1.055)}{0.11793-0.055} = \$125.6 \text{ million}$$

The total value of operations is:

$$\begin{aligned} V_{op} &= \frac{\$1.3720}{(1+0.11793)^1} + \frac{\$3.7719}{(1+0.11793)^2} + \frac{\$6.2574}{(1+0.11793)^3} \\ &\quad + \frac{\$7.1259}{(1+0.11793)^4} + \frac{\$7.4931+\$126.6}{(1+0.11793)^5} \\ &= \$89.5 \text{ million} \end{aligned}$$

This is the same value of operations we obtained previously by separately finding the value of unlevered operations and the value of the tax shield. Although this compressed approach requires fewer calculations, we prefer to separately value the FCF and the tax savings because this shows us how much value is being added by the unlevered operations and how much by the choice of capital structure.

21-5d Valuation Using the FCFE Model

The horizon value of Tutwiler's free cash flows to equity can be calculated using the constant growth formula of Equation 21-22:[7]

$$HV_{FCFE,2021} = \frac{FCF_{2021}(1+g_L)}{r_{sL}-g_L} = \frac{\$6.2359(1.055)}{0.13-0.055} = \$87.7 \text{ million}$$

Notice that this horizon value is different from that of the compressed APV model and FCF corporate valuation model. That is because the FCFE horizon value is only for equity, whereas the other two horizon values are for the total value of operations. If the 2021 debt of $37.9 million shown in Row 7 of Table 21-2 is added to the $87.7 $HV_{FCFE,2021}$, the result is $125.6 million, the same horizon value of operations obtained with the FCF corporate valuation model and compressed APV model.

Row 17 in Table 21-2 shows the yearly projections of FCFE. Using Equation 21-23, the value of the free cash flow to equity is:

$$\begin{aligned} V_{FCFE} &= \frac{\$1.71}{(1+0.13)^1} + \frac{\$3.47}{(1+0.13)^2} + \frac{\$5.27}{(1+0.13)^3} \\ &\quad + \frac{\$5.93}{(1+0.13)^4} + \frac{\$6.24+\$87.72}{(1+0.13)^5} \\ &= \$62.5 \text{ million} \end{aligned}$$

Because Tutwiler has no nonoperating assets, its total intrinsic equity value is equal to the V_{FCFE} of $62.5 million. Notice that this is the same value given by the FCF corporate valuation model and the compressed APV approach.

[7]Note that we report two decimal places for the 2021 FCFE even though Table 21-2 reports only one decimal place. All calculations are performed using the full nonrounded values in the *Excel* file ***Ch21 Tool Kit.xlsx***.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

As mentioned previously, the FCF corporate valuation model and the FCFE model are not appropriate if the capital structure is not constant during the forecast period. However, the compressed APV approach is appropriate for such situations, as illustrated in the next section.

SELF-TEST

How do the FCFE, APV, and corporate valuation approaches differ from one another? How are they similar?

21-6 Analysis of a Dynamic Capital Structure

Tutwiler currently has equity worth $62.5 million and debt of $27 million, giving it a capital structure financed with about 30% debt: $\$27.0/(\$62.5 + \$27.0) = 0.302 = 30.2\%$. Suppose Tutwiler has decided to increase its debt from 30% to 50% over the next 5 years and to maintain the new capital structure thereafter. How would this affect Tutwiler's valuation? The free cash flows and unlevered cost of equity will not change, but the annual interest tax shields and the long-term WACC will change. At a 30% debt level, the interest rate on Tutwiler's debt was 9%. However, at higher debt levels, Tutwiler is more risky, and its interest rate will rise to 9.5% to reflect this additional risk.[8] Because the capital structure is changing, we can use only the compressed APV for this analysis.

21-6a The Dynamic Capital Structure's Effect on the Tax Shield

resource

*See **Web Extension 21A** and **Ch21 Tool Kit.xlsx** on the textbook's Web site.*

Tutwiler will increase its debt during the first 5 years to reach its long-run target capital structure of 50% debt. With more debt and a higher interest rate, the interest payments will be higher than those shown in Table 21-2, thus increasing the tax savings. The new interest payments and tax savings with more debt and a higher interest rate are projected as follows:

	1/1/17	12/31/17	12/31/18	12/31/19	12/31/20	12/31/21
Debt	$36.0000	$44.0000	$54.0000	$62.0000	$70.5621	$74.4430
Interest		$3.4200	$4.1800	$5.1300	$5.8900	$6.7034
Interest tax savings		$1.3680	$1.6720	$2.0520	$2.3560	$2.6814

Tutwiler immediately will increase its debt from $27 million to $36 million and then increase the debt each year to reach its target capital structure of 50% debt and 50% equity by the start of 2021.[9]

Based on the new tax shields, the tax shield horizon value in 2021 is:

$$HV_{TS,2021} = \frac{TS_{2021}(1 + g_L)}{r_{sU} - g_L} = \frac{\$2.6814(1.055)}{0.11793 - 0.055} = \$44.95$$

[8]We are assuming for simplicity that its higher risk will not affect the expected free cash flows. In practice, it is extremely difficult to estimate the impact on free cash flow of expected bankruptcy costs. However, these costs can be significant and should be considered when a very high degree of leverage is being used.

[9]The last year's projected interest expense must be consistent with the assumed capital structure in order to use the relation $TS_{N+1} = TS_N(1 + g)$ in calculating the tax shield horizon value.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The total value of the tax shields is:

$$V_{\text{Tax shield}} = \frac{\$1.3680}{(1+0.11793)^1} + \frac{\$1.6720}{(1+0.11793)^2} + \frac{\$2.0520}{(1+0.11793)^3} + \frac{\$2.3560}{(1+0.11793)^4} + \frac{\$2.6814 + \$44.95}{(1+0.11793)^5}$$
$$= \$32.8 \text{ million}$$

21-6b The Dynamic Capital Structure's Effect on Value

The free cash flows are unchanged, so the value of the unlevered firm is the same as calculated previously in Section 21-5c, which is $73.0. The value of the tax shield is $32.8 million, as calculated in Section 21-6a. Therefore, the total value of operations is:

$$V_{op} = \$73.0 + \$32.8 = \$105.8 \text{ million}$$

The debt level immediately increased from $27 million to $36 million, so the intrinsic value of equity is:

$$\text{Intrinsic value of equity} = V_{op} + \text{Nonoperating assets} - \text{Debt}$$
$$= \$105.8 + \$0 - \$36.0 = \$69.8 \text{ million}$$

With a 30% constant capital structure, Tutwiler's intrinsic value of equity was $62.5 million, as calculated three different ways in Section 21-5. Therefore, the change in capital structure increased the intrinsic value of equity by about $7.3 million: $69.8 − $62.5 = $7.3.

SELF-TEST

Why is the compressed adjusted present value approach appropriate for situations with a changing capital structure?

Describe the steps required to apply the compressed APV approach.

A company forecasts free cash flow of $400 at Year 1, $600 at Year 2; after Year 2, the FCF grow at a constant rate of 5%. The company forecasts the tax savings from interest deductions as $200 in Year 1, $100 in Year 2; after Year 2, the tax savings grow at a constant rate of 5%. The unlevered cost of equity is 9%. What is the horizon value of operations at Year 2? **($15,750.0)** *What is the current unlevered value of operations?* **($14,128.4)** *What is the horizon value of the tax shield at Year 2?* **($2,625.0)** *What is the current value of the tax shield?* **($2,477.1)** *What is the levered value of operations at Year 0?* **($16,605.5)**

SUMMARY

In this chapter we discussed a variety of topics related to capital structure decisions. The key concepts covered are listed here.

- The most general approach to analyzing capital structure effects expresses the levered value of a company as the combination of its unlevered value and the value of side effects due to leverage:

$$V_L = V_U + \text{Value of side effects}$$

- MM stated that the primary benefit of debt stems from the *tax deductibility of interest payments*. The present value of the tax savings due to interest expense deductibility is called the **tax shield**. If we ignore other side effects, the value of an unlevered firm is:

$$V_L = V_U + V_{\text{Tax shield}}$$

- The **compressed adjusted present value (CAPV)** model incorporates nonconstant growth and assumes that the tax savings should be discounted at the unlevered cost of equity.
- The levered cost of equity and the levered beta are different in the compressed APV model than in the MM and Hamada models. In the compressed APV model, the relationships are:

$$r_{sL} = r_{sU} + (r_{sU} - r_d)\left(\frac{w_d}{w_S}\right)$$

and

$$b = b_U + (b_U - b_D)\left(\frac{w_d}{w_S}\right)$$

QUESTIONS

(21-1) Define each of the following terms:

a. Interest tax shields; value of tax shield
b. Adjusted present value (APV) model
c. Compressed adjusted present value (CAPV) model

(21-2) Modigliani and Miller assumed that firms do not grow. How does positive growth change their conclusions about the value of the levered firm and its cost of capital?

SELF-TEST PROBLEM — Solution Shown in Appendix A

(ST-1) Value of a Levered Firm

The Menendez Corporation forecasts free cash flow of $100 at Year 1 and $120 at Year 2; after Year 2, the FCF is expected to grow at a constant rate of 4%. The company has a tax rate of 40% and $500 in debt at an interest rate of 5%. The company plans to hold debt steady until after Year 2, after which the debt (and tax savings) will grow at a constant rate of 4%. The unlevered cost of equity is 8%. Using the compressed APV model, answer the following questions.

a. What is the horizon value of operations at Year 2?
b. What is the current unlevered value of operations?
c. What are the tax savings for Year 1 and Year 2 (*Hint:* They are identical because the debt doesn't change.)
d. What is the horizon value of the tax shield at Year 2?
e. What is the current value of the tax shield?
f. What is the levered value of operations at Year 0?

PROBLEMS

Answers Are in Appendix B

EASY PROBLEMS 1–3

(21-1) MM Model with Zero Taxes

An unlevered firm has a value of $500 million. An otherwise identical but levered firm has $50 million in debt. Under the MM zero-tax model, what is the value of the levered firm?

(21-2) MM Model with Corporate Taxes

An unlevered firm has a value of $800 million. An otherwise identical but levered firm has $60 million in debt at a 5% interest rate. Its cost of debt is 5% and its unlevered cost of equity is 11%. No growth is expected. Assuming the corporate tax rate is 35%, use the MM model with corporate taxes to determine the value of the levered firm.

(21-3) Compressed APV Model with Constant Growth

An unlevered firm has a value of $800 million. An otherwise identical but levered firm has $60 million in debt at a 5% interest rate. Its cost of debt is 5% and its unlevered cost of equity is 11%. After Year 1, free cash flows and tax savings are expected to grow at a constant rate of 3%. Assuming the corporate tax rate is 35%, use the compressed adjusted present value model to determine the value of the levered firm. (*Hint:* The interest expense at Year 1 is based on the current level of debt.)

INTERMEDIATE PROBLEMS 4–5

(21-4) Business and Financial Risk—MM Model

Air Tampa has just been incorporated, and its board of directors is grappling with the question of optimal capital structure. The company plans to offer commuter air services between Tampa and smaller surrounding cities. Jaxair has been around for a few years, and it has about the same basic business risk as Air Tampa would have. Jaxair's market-determined beta is 1.8, and it has a current market value debt ratio (total debt to total assets) of 50% and a federal-plus-state tax rate of 40%. Air Tampa expects to be only marginally profitable at start-up; hence, its tax rate would only be 25%. Air Tampa's owners expect that the total book and market value of the firm's stock, if it uses zero debt, would be $10 million. Air Tampa's CFO believes that the MM and Hamada formulas for the value of a levered firm and the levered firm's cost of capital should be used because zero growth is expected.

a. Estimate the beta of an unlevered firm in the commuter airline business based on Jaxair's market-determined beta.
b. Now assume that $r_d = r_{RF} = 10\%$ and that the market risk premium $RP_M = 5\%$. Find the required rate of return on equity for an unlevered commuter airline.
c. Air Tampa is considering three capital structures: (1) $2 million debt, (2) $4 million debt, and (3) $6 million debt. Estimate Air Tampa's r_s for these debt levels.
d. Calculate Air Tampa's r_s at $6 million debt while assuming its federal-plus-state tax rate is now 40%. Compare this with your corresponding answer to Part c. (*Hint:* The increase in the tax rate causes V_U to drop to $8 million.)

(21-5) MM with Corporate Taxes

Companies U and L are identical in every respect except that U is unlevered while L has $10 million of 5% bonds outstanding. Assume that: (1) All of the MM assumptions are met. (2) Both firms are subject to a 40% federal-plus-state corporate tax rate. (3) EBIT is $2 million. (4) The unlevered cost of equity is 10%.

a. What value would MM now estimate for each firm? (*Hint:* Use Proposition I.)
b. What is r_s for Firm U? For Firm L?
c. Find S_L, and then show that $S_L + D = V_L$ results in the same value as obtained in Part a.
d. What is the WACC for Firm U? For Firm L?

CHALLENGING PROBLEMS 6–7

(21-6) Compressed Adjusted Present Value

Schwarzentraub Corporation's expected free cash flow for the year is $500,000; in the future, free cash flow is expected to grow at a rate of 9%. The company currently has no debt, and its cost of equity is 13%. Its tax rate is 40%. Use the compressed adjusted value approach to answer the following questions.

a. Find V_U.
b. Find V_L and r_{sL} if Schwarzentraub uses $5 million in debt with a cost of 7%. Use the APV model that allows for growth.
c. Based on V_U from Part a, find V_L and r_{sL} using the MM model (with taxes) if Schwarzentraub uses $5 million in 7% debt.
d. Explain the difference between your answers to Parts b and c.

(21-7) Compressed APV with Nonconstant Growth

Sheldon Corporation projects the following free cash flows (FCFs) and interest expenses for the next 3 years, after which FCF and interest expenses are expected to grow at a constant 7% rate. Sheldon's unlevered cost of equity is 13%; its tax rate is 40%.

	Year		
	1	2	3
Free cash flow ($ millions)	$20	$30	$40
Interest expense ($ millions)	$8	$9	$10

a. What is Sheldon's unlevered horizon value of operations at Year 3?
b. What is the current unlevered value of operations?
c. What is the horizon value of the tax shield at Year 3?
d. What is the current value of the tax shield?
e. What is the current total value of the company?

SPREADSHEET PROBLEM

(21-8) Build a Model: Compressed Adjusted Value Model

Start with the partial model in the file ***Ch21 P08 Build a Model.xlsx*** on the textbook's Web site. Kasperov Corporation has an unlevered cost of equity of 12% and is taxed at a 40% rate. The 4-year forecasts of free cash flow and interest expenses are shown in the following table; free cash flow and interest expenses are expected to grow at a 5% rate after Year 4. Using the compressed APV model, answer the following questions.

INPUTS (In Millions)	Projected			
Year:	1	2	3	4
Free cash flow	$200	$280	$320	$340
Interest expense	$100	$120	$120	$140

a. Calculate the estimated horizon value of unlevered operations at Year 4 (i.e., immediately after the Year-4 free cash flow).
b. Calculate the current value of unlevered operations.
c. Calculate the estimated horizon value of the tax shield at Year 4 (i.e., immediately after the Year-4 free cash flow).
d. Calculate the current value of the tax shield.
e. Calculate the current total value.

MINI CASE

David Lyons, CEO of Lyons Solar Technologies, is concerned about his firm's level of debt financing. The company uses short-term debt to finance its temporary working capital needs, but it does not use any permanent (long-term) debt. Other solar technology companies average about 30% debt, and Mr. Lyons wonders why they use so much more debt and how it affects stock prices. To gain some insights into the matter, he poses the following questions to you, his recently hired assistant.

a. Who were Modigliani and Miller (MM), and what assumptions are embedded in the MM and Miller models?
b. Assume that Firms U and L are in the same risk class and that both have EBIT = $500,000. Firm U uses no debt financing, and its cost of equity is $r_{sU} = 14\%$. Firm L has $1 million of debt outstanding at a cost of $r_d = 8\%$. There are no taxes. Assume that the MM assumptions hold.
   (1) Find V, S, r_s, and WACC for Firms U and L.
   (2) Graph (a) the relationships between capital costs and leverage as measured by D/V and (b) the relationship between V and D.
c. Now assume that Firms L and U are both subject to a 40% corporate tax rate. Using the data given in Part b, repeat the analysis called for in b(1) and b(2) using assumptions from the MM model with taxes.
d. Suppose that Firms U and L are growing at a constant rate of 7% and that the investment in net operating assets required to support this growth is 10% of EBIT. Use the compressed adjusted present value (APV) model to estimate the value of U and L. Also estimate the levered cost of equity and the weighted average cost of capital.
e. Suppose the expected free cash flow for Year 1 is $250,000 but it is expected to grow unevenly over the next 3 years: FCF2 = $290,000 and FCF3 = $320,000, after which it will grow at a constant rate of 7%. The expected interest expense at Year 1 is $80,000, but it is expected to grow over the next couple of years before the capital structure becomes constant: Interest expense at Year 2 will be $95,000, at Year 3 it will be $120,000, and it will grow at 7% thereafter. What is the estimated horizon unlevered value of operations (i.e., the value at Year 3 immediately after the FCF at Year 3)? What is the current unlevered value of operations? What is the horizon value of the tax shield at Year 3? What is the current value of the tax shield? What is the current total value? The tax rate and unlevered cost of equity remain at 40% and 14%, respectively.

SELECTED ADDITIONAL CASES

The following cases from CengageCompose cover many of the concepts discussed in this chapter and are available at **http://compose.cengage.com.**

Klein-Brigham Series:
Case 7, "Seattle Steel Products"; Case 9, "Kleen Kar, Inc."; Case 10, "Aspeon Sparkling Water"; Case 43, "Mountain Springs"; Case 57, "Greta Cosmetics"; Case 74, "The Western Company"; Case 83, "Armstrong Production Company"; and Case 99, "Moore Plumbing Supply Company," focus on capital structure theory. Case 8, "Johnson Window Company," and Case 56, "Isle Marine Boat Company," cover operating and financial leverage.

Brigham-Buzzard Series:
Case 8, "Powerline Network Corporation," covers operating leverage, financial leverage, and the optimal capital structure.

CHAPTER 22

Mergers and Corporate Control

Verizon Communications made Verizon Wireless into a wholly owned subsidiary in 2014 with a $130 billion deal to acquire all the Verizon Wireless stock that it did not already own. What does this have to do with Vodafone Group, a UK telecommunications company? The story began in 1999 when Vodafone entered a joint venture with Bell Atlantic, resulting in a mobile technology subsidiary called Verizon Wireless. At about the same time, Bell Atlantic merged with GTE, the largest of the original Bell system companies. The merged companies became Verizon Communications and owned 55% of the Verizon Wireless subsidiary; Vodafone retained a 45% share in Verizon Wireless.

Vodafone soon made news in 2000 with its hostile takeover of Mannesmann AG, a German technology giant, in a deal valued at $161 billion, the largest merger in history. Through acquisitions and growth of its existing operations, Vodafone became one of the two largest wireless phone companies in the world, second only to China Mobile.

Fast-forward to 2014. To obtain Vodafone's 45% interest in Verizon Wireless, Verizon Communications gave Vodafone over 1.2 million shares of Verizon Communications stock (worth about $60.2 billion) and paid around $70 billion in cash (and other financial assets). Vodafone then gave each of its own shareholders a proportional amount of the Verizon Communications stock and paid its shareholders about $24 billion in a cash distribution.

Think about these transactions as you read the chapter.

Most corporate growth occurs by *internal expansion*, which takes place when a firm's existing divisions grow through normal capital budgeting activities. However, the most dramatic examples of growth result from mergers, the first topic covered in this chapter. Other actions that alter corporate control are divestitures—conditions change over time, causing firms to sell off, or divest, major divisions to other firms that can better utilize the divested assets. A *holding company* is another form of corporate control in which one corporation controls other companies by owning some, or all, of their stocks.

22-1 Rationale for Mergers

Many reasons have been proposed by financial managers and theorists to account for the high level of U.S. merger activity. The primary motives behind corporate **mergers** are presented in this section.[1]

22-1a Synergy

The primary motivation for most mergers is to increase the value of the combined enterprise. If Companies A and B merge to form Company C and if C's value exceeds that of A and B taken together, then **synergy** is said to exist, and such a merger should be beneficial to both A's and B's stockholders.[2] Synergistic effects can arise from five sources: (1) *operating economies*, which result from **economies of scale** in management, marketing, production, or distribution in which larger companies can reduce costs, increase sales, or both; (2) *financial economies*, including lower transaction costs and better coverage by security analysts; (3) *tax effects*, in which case the combined enterprise pays less in taxes than the separate firms would pay; (4) *differential efficiency*, which implies that the management of one firm is more efficient and that the weaker firm's assets will be more productive after the merger; and (5) *increased market power* due to reduced competition. Operating and financial economies are socially desirable, as are mergers that increase managerial efficiency, but mergers that reduce competition are socially undesirable and illegal.[3]

Expected synergies are not always realized. For example, when AOL acquired Time Warner, it believed that Time Warner's extensive content library could be sold to AOL's Internet subscribers and that AOL subscribers could be shifted over to Time Warner's cable system. When the merger was announced, the new management estimated that such synergies would increase operating income by $1 billion per year. However, things didn't work out as expected, and in 2002 Time Warner had to write off about $100 billion in lost value associated with the merger.

Merrill Lynch (ML) was facing bankruptcy in late 2008, so federal officials encouraged Bank of America (BofA) to save ML from bankruptcy by acquiring it, creating one of the world's largest (if not the largest) financial conglomerate. But BofA tried to back out

[1] As we use the term, *merger* means any combination that forms one economic unit from two or more previous ones. For legal purposes, there are distinctions among the various ways these combinations can occur, but our focus is on the fundamental economic and financial aspects of mergers.

[2] If synergy exists, then the whole is greater than the sum of the parts. Synergy is also called the "2 plus 2 equals 5 effect." The distribution of the synergistic gain between A's and B's stockholders is determined by negotiation. This point is discussed later in the chapter.

[3] In the 1880s and 1890s, many mergers occurred in the United States, and some of them were directed toward gaining market power rather than increasing efficiency. As a result, Congress passed a series of acts designed to ensure that mergers were not used to reduce competition. The principal acts include the Sherman Act (1890), the Clayton Act (1914), and the Celler Act (1950). These acts make it illegal for firms to combine if the combination tends to lessen competition. The acts are enforced by the Antitrust Division of the Justice Department and by the Federal Trade Commission.

of the deal as it learned more about ML's situation. Under pressure from the government, BofA went through with the merger and almost immediately reported over $21 billion in associated losses.

As these examples illustrate, often it is blemishes, not synergies, that materialize after a merger.

22-1b Tax Considerations

Tax considerations have stimulated a number of mergers. For example, a profitable firm in the highest tax bracket could acquire a firm with large accumulated tax losses. These losses could then be turned into immediate tax savings rather than carried forward and used in the future.[4]

Also, mergers can serve as a way of minimizing taxes when disposing of excess cash. For example, if a firm has a shortage of internal investment opportunities compared with its free cash flow, it could: (1) pay an extra dividend, (2) invest in marketable securities, (3) repurchase its own stock, or (4) purchase another firm. If it pays an extra dividend, its stockholders would have to pay immediate taxes on the distribution. Marketable securities often provide a good temporary parking place for money, but they generally earn a rate of return less than that required by stockholders. A stock repurchase might result in a capital gain for the selling stockholders. However, using surplus cash to acquire another firm would avoid all these problems, and this has motivated a number of mergers. Still, as we discuss later, the tax savings are often less than the premium paid in the acquisition. Thus, mergers motivated only by tax considerations often reduce the acquiring shareholders' wealth.

22-1c Purchase of Assets below Their Replacement Cost

Sometimes a firm will be touted as an acquisition candidate because the cost of replacing its assets is considerably higher than its market value. This is especially true in the natural resources industry; for example, an oil company's reserves might be worth more on paper than the company's stock. (Of course, converting paper value to monetary value isn't always as easy as it sounds.)

22-1d Diversification

Managers often cite diversification as a reason for mergers. They contend that diversification helps stabilize a firm's earnings and thus benefits its owners. Stabilization of earnings is certainly beneficial to employees, suppliers, and customers, but its value to stockholders is less certain. Why should Firm A acquire Firm B to stabilize earnings when stockholders can simply buy the stocks of both firms? Indeed, research suggests that in most cases diversification does not increase the firm's value. In fact, many studies find that diversified firms are worth significantly *less* than the sum of their individual parts.[5]

Of course, if you were the owner-manager of a closely held firm, it might be nearly impossible to sell part of your stock to diversify. Also, selling your stock would probably

[4]Mergers undertaken only to use accumulated tax losses would probably be challenged by the IRS. In recent years, Congress has made it increasingly difficult for firms to pass along tax savings after mergers. Internal Revenue Code Section 382 spells out the limitations on the use of loss carryforwards in a merger.

[5]See, for example, Philip Berger and Eli Ofek, "Diversification's Effect on Firm Value," *Journal of Financial Economics*, 1995, pp. 37–65; and Larry Lang and René Stulz, "Tobin's Q, Corporate Diversification, and Firm Performance," *Journal of Political Economy*, December 1994, pp. 1248–1280.

lead to a large capital gains tax. So, a diversification merger might be the best way to achieve personal diversification for a privately held firm.

22-1e Managers' Personal Incentives

Financial economists like to think that business decisions are based only on economic considerations, especially maximization of firms' values. However, many business decisions are based more on managers' personal motivations than on economic analyses. Business leaders like power, and more power is attached to running a larger corporation than a smaller one. Most likely, no executive would admit that his or her ego was the primary reason behind a merger, but egos do play a prominent role in many mergers.[6]

It has also been observed that executive salaries are highly correlated with company size—the bigger the company, the higher the salaries of its top officers. This, too, could obviously cause unnecessary acquisitions, as managers seek to increase the size of their companies as a way of increasing their own compensation.

Personal considerations deter as well as motivate mergers. After most takeovers, some managers of the acquired companies lose their jobs, or at least their autonomy. Therefore, managers who own less than 51% of their firms' stock look to devices that will lessen the chances of a takeover, and a merger can serve as such a device. In 2005, for example, MCI's board of directors, over the objections of large shareholders, turned down repeated acquisition offers from Qwest, at the time the nation's fourth-largest local phone company, in favor of substantially smaller offers from Verizon, the nation's largest phone company. MCI's management viewed Verizon as a stronger, more stable partner than Qwest even though Qwest's bid was at times 20% higher than Verizon's. In response to management's refusal to accept the higher bid, the holders of some 28% of MCI's stock withheld their votes to re-elect the board of directors as a protest. Nonetheless, management proceeded with the Verizon merger negotiations, and the two companies merged in June 2006. In such cases, management always argues that synergy, not a desire to protect their own jobs, is the motivation for the choice. However, it is difficult to rationalize rejecting a 20% larger bid for undocumented synergies, and some observers suspect that this merger—like many others—was ultimately designed to benefit managers rather than shareholders.

22-1f Breakup Value

Some takeover specialists estimate a company's **breakup value**, which is the value of the individual parts of the firm if they were sold off separately. If this value is higher than the firm's current market value, then a takeover specialist could acquire the firm at or even above its current market value, sell it off in pieces, and earn a profit.

SELF-TEST

Define synergy. *Is synergy a valid rationale for mergers? Describe several situations that might produce synergistic gains.*

Suppose your firm could purchase another firm for only half of its replacement value. Would that be a sufficient justification for the acquisition? Why or why not?

Discuss the pros and cons of diversification as a rationale for mergers.

What is breakup value?

---

22-2 Types of Mergers

Economists classify mergers into four types: (1) horizontal, (2) vertical, (3) congeneric, and (4) conglomerate. A **horizontal merger** occurs when one firm combines with another in its same line of business—the 2014 proposed Comcast–Time Warner merger and the 2013 Amgen–Onyx Pharmaceuticals merger are examples. An example of a **vertical merger** would be a steel producer's acquisition of one of its own suppliers, such as an iron or coal mining firm, or an oil producer's acquisition of a petrochemical firm that uses oil as a raw material. *Congeneric* means "allied in nature or action"; hence, a **congeneric merger** involves related enterprises but not producers of the same product (horizontal) or firms in a producer–supplier relationship (vertical). Facebook's 2014 acquisition of WhatsApp is an example. A **conglomerate merger** occurs when unrelated enterprises combine.

Operating economies (and also anticompetitive effects) are at least partially dependent on the type of merger involved. Vertical and horizontal mergers generally provide the greatest synergistic operating benefits, but they are also the ones most likely to be attacked by the Department of Justice as being anticompetitive.[7] In any event, it is useful to think of these economic classifications when analyzing prospective mergers.

SELF-TEST

What are the four types of mergers?

22-3 Level of Merger Activity

Five principal "merger waves" have occurred in the United States. The first was in the late 1800s, when consolidations occurred in the oil, steel, tobacco, and other basic industries. The second was in the 1920s, when the stock market boom helped financial promoters consolidate firms in a number of industries, including utilities, communications, and autos. The third was in the 1960s, when conglomerate mergers were the rage. The fourth occurred in the 1980s, when LBO firms and others began using junk bonds to finance all manner of acquisitions. The fifth, which involves strategic alliances designed to enable firms to compete better in the global economy, lasted throughout the 1990s. Some speculate that the 2000s were a sixth wave, driven by private equity.

As shown in Table 22-1, some huge mergers have occurred. Most recent mergers have been strategic in nature—companies are merging to gain economies of scale or scope and thus be better able to compete in the world economy. Indeed, many recent mergers have involved companies in the financial, defense, media, computer, telecommunications, and health care industries, all of which are experiencing structural changes and intense competition.

In the 1980s, cash was the preferred method of payment, because large cash payments could convince even the most reluctant shareholder to approve the deal. However, the cash was generally obtained by borrowing, leaving the consolidated company with a heavy debt burden, which often led to difficulties. Through the mid-2010s, stock replaced borrowed cash as the merger currency for two reasons: (1) Many of the 1980s mergers were financed with junk bonds that later went into default. These defaults, along with the demise of Drexel Burnham, the leading junk bond dealer, have made it difficult to arrange debt-financed mergers. (2) Many of the mergers during that time were for strategic

[7]For interesting insights into antitrust regulations and mergers, see B. Espen Eckbo, "Mergers and the Value of Antitrust Deterrence," *Journal of Finance*, July 1992, pp. 1005–1029.

reasons, such as Eli Lilly's $6.5 billion acquisition of ImClone Systems in 2008, or for industry consolidation purposes, such as Sprint's acquisition of Clearwire in 2013. Most of these mergers have been friendly, and stock swaps are easier to arrange in friendly mergers than in hostile ones. Global merger activity declined significantly in the 4 years after the 2007–2008 financial crisis and subsequent recession but has since picked up.

There has also been an increase in cross-border mergers. For example, in 2011 the Swiss automation technology company ABB acquired Baldor Electric Company, a U.S.-based industrial motors manufacturer. Also in early 2011, PepsiCo acquired a 66% interest in the Russian food company Wimm-Bill-Dann Foods and purchased the remaining shares in late 2011.

SELF-TEST

What major "merger waves" have occurred in the United States?

22-4 Hostile versus Friendly Takeovers

In the vast majority of merger situations, one firm (generally the larger of the two) simply decides to buy another company, negotiates a price with the management of the target firm, and then acquires the target company. Occasionally, the acquired firm will initiate the action, but it is much more common for a firm to seek companies to acquire than to seek to be acquired. Following convention, we call a company that seeks to acquire another firm the **acquiring company** and the one that it seeks to acquire the **target company**.

Once an acquiring company has identified a possible target, it must: (1) establish a suitable price, or range of prices, and (2) decide on the terms of payment—will it offer cash, its own common stock, bonds, or some combination? Next, the acquiring firm's managers must decide how to approach the target company's managers. If the acquiring firm has reason to believe that the target's management will approve the merger, then one CEO will contact the other, propose a merger, and then try to work out suitable terms. If an agreement is reached, then the two management groups will issue statements to their stockholders indicating that they approve the merger, and the target firm's management

will recommend to its stockholders that they agree to the merger. Generally, the stockholders are asked to *tender* (or send in) their shares to a designated financial institution, along with a signed power of attorney that transfers ownership of the shares to the acquiring firm. The target firm's stockholders then receive the specified payment, either common stock of the acquiring company (in which case the target company's stockholders become stockholders of the acquiring company), cash, bonds, or some mix of cash and securities. This is a **friendly merger**. Sprint's acquisition of Clearwire in 2013 is an example of a friendly merger, even though Clearwire entertained an offer from Dish Network after an initial offer from Sprint was too low.

Often, however, the target company's management resists the merger. Perhaps they feel that the price offered is too low, or perhaps they simply want to keep their jobs. Regardless of the reasons, in this case the acquiring firm's offer is said to be **hostile** rather than friendly, and the acquiring firm must make a direct appeal to the target firm's stockholders. In a hostile merger, the acquiring company will again make a **tender offer**, and again it will ask the stockholders of the target firm to tender their shares in exchange for the offered price. This time, though, the target firm's managers will urge stockholders not to tender their shares, generally stating that the price offered (cash, bonds, or stocks in the acquiring firm) is too low. For example, in late 2010 the board of directors for the biotech company Genzyme refused to consider a $69 per share offer from French pharmaceutical giant Sanofi. To encourage the board to actively consider the offer, Sanofi appealed directly to Genzyme's shareholders with a tender offer at $69 per share. The tender offer got the attention of Genzyme's board and in early 2011, Sanofi increased the cash component of the offer to $74 and added a security called a contingent value right (CVR) to the mix. The CVR would pay up to $14 per share more to the selling shareholders, depending on performance of one of Genzyme's drugs, and the merger was finally approved by management.[8]

Although most mergers are friendly, there are cases in which high-profile firms have attempted hostile takeovers. For example, Wachovia, before its acquisition by Wells Fargo during the financial crisis in 2008, defeated a hostile bid by SunTrust and was acquired, instead, by First Union. Looking overseas, Olivetti successfully conducted a hostile takeover of Telecom Italia, and, in another hostile telecommunications merger, Britain's Vodafone AirTouch acquired its German rival, Mannesmann AG.

Perhaps not surprisingly, hostile bids often fail. However, an all-cash offer that is high enough will generally overcome any resistance by the target firm's management. A hostile merger often begins with a "preemptive" or "blowout" bid. The idea is to offer a very high premium over the pre-announcement price to achieve two goals: (1) No other bidders will be willing to jump into the fray. (2) The target company's board cannot simply reject the bid. If a hostile bid is eventually accepted by the target's board, then the deal ends up as "friendly," despite any acrimony during the hostile phase.

SELF-TEST

What is the difference between a hostile and a friendly merger?

22-5 Merger Regulation

Prior to the mid-1960s, friendly acquisitions generally took place as simple exchange-of-stock mergers, and a proxy fight was the primary weapon used in hostile control battles. In the mid-1960s, however, corporate raiders began to operate differently. First, it took

[8]See **www.bloomberg.com/news/2011-02-16/sanofi-aventis-agrees-to-buy-genzyme-for-74-a-share-in-19-2-billion-deal.html** for more information on the Sanofi-Genzyme acquisition.

a long time to mount a proxy fight—raiders had to first request a list of the target company's stockholders, be refused, and then get a court order forcing management to turn over the list. During that time, the target's management could think through and then implement a strategy to fend off the raider. As a result, management won most proxy fights.

Then raiders thought, "If we could bring the decision to a head quickly, before management can take countermeasures, it would greatly increase our probability of success." That led the raiders to turn from proxy fights to tender offers, which had a much shorter response time. For example, the stockholders of a company whose stock was selling for $20 might be offered $27 per share and be given two weeks to accept. The raider, meanwhile, would have accumulated a substantial block of the shares in open market purchases, and additional shares might have been purchased by institutional friends of the raider who promised to tender their shares in exchange for the tip that a raid was to occur.

Faced with a well-planned raid, managements were generally overwhelmed. The stock might actually be worth more than the offered price, but management simply did not have time to get this message across to stockholders or to find a competing bidder. This situation seemed unfair, so Congress passed the Williams Act in 1968. This law had two main objectives: (1) to regulate the way acquiring firms can structure takeover offers and (2) to force acquiring firms to disclose more information about their offers. In essence, Congress wanted to put target managements in a better position to defend against hostile offers. Additionally, Congress believed that shareholders needed easier access to information about tender offers—including information on any securities that might be offered in lieu of cash—in order to make rational tender-versus-don't-tender decisions.

The Williams Act placed the following four restrictions on acquiring firms: (1) Acquirers must disclose their current holdings and future intentions within 10 days of amassing at least 5% of a company's stock. (2) Acquirers must disclose the source of the funds to be used in the acquisition. (3) The target firm's shareholders must be allowed at least 20 days to tender their shares; that is, the offer must be "open" for at least 20 days. (4) If the acquiring firm increases the offer price during the 20-day open period, then all shareholders who tendered prior to the new offer must receive the higher price. In total, these restrictions were intended to reduce the acquiring firm's ability to surprise management and to stampede target shareholders into accepting an inadequate offer. Prior to the Williams Act, offers were generally made on a first-come, first-served basis, and they were often accompanied by an implicit threat to lower the bid price after 50% of the shares were in hand. The legislation also gave the target more time to mount a defense, and it gave rival bidders and white knights a chance to enter the fray and thus help a target's stockholders obtain a better price.

Many states have also passed laws designed to protect firms in their states from hostile takeovers. In 1987 the U.S. Supreme Court upheld an Indiana law that radically changed the rules of the takeover game. Specifically, the Indiana law first defined "control shares" as enough shares to give an investor 20% of the vote. It went on to state that when an investor buys control shares, those shares can be voted only after approval by a majority of "disinterested shareholders," defined as those who are neither officers nor inside directors of the company nor associates of the raider. The law also gives the buyer of control shares the right to insist that a shareholders' meeting be called within 50 days to decide whether the shares may be voted. The Indiana law dealt a major blow to raiders, mainly because it slows down the action and thus gives the target firm time to mount a defense. Delaware (the state in which most large companies are incorporated) later passed a similar bill, as did New York and a number of other important states.

State laws also have some features that protect target stockholders from their own managers. Included are limits on the use of golden parachutes, onerous debt financing plans, and some types of takeover defenses. Because these laws do not regulate tender offers per se but rather govern the practices of firms in the state, they have withstood all legal challenges to date. But when companies such as IBM offer 100% premiums for companies such as Lotus, it is hard for any defense to hold them off.

SELF-TEST

Is there a need to regulate mergers? Explain.

Do the states play a role in merger regulation, or is it all done at the national level? Explain.

22-6 Overview of Merger Analysis

An acquiring firm must answer two questions. First, how much would the target be worth after being incorporated into the acquirer? Notice that this may be quite different from the target's current value, which does not reflect any post-merger synergies or tax benefits. Second, how much should the acquirer offer for the target? A low price is obviously better for the acquirer, but the target won't take the offer if it is too low. However, a higher offer price could scare off potential rival bidders. Later sections discuss setting the offer's price and structure (cash versus stock), but for now we focus on estimating the post-merger value of the target.

There are two basic approaches used in merger valuation: discounted cash flow (DCF) techniques and market multiple analysis.[9] Survey evidence shows that virtually all investment banks use DCF techniques to estimate the current value of a target.[10] As part of the process, all respondents used constant growth models and market multiples to estimate the horizon value. The market multiple approach assumes that a target is directly comparable to the average firm in its industry. Because this procedure provides at best a ballpark estimate, we will focus on discounted cash flow approaches.

There are three widely used DCF methods: (1) the free cash flow corporate valuation method, (2) the compressed adjusted present value method, and (3) the free cash flow to equity method, which is also called the equity residual method. As we explained in Chapter 21, the compressed adjusted value is the only appropriate model if there is a nonconstant capital structure during the explicit forecast period, something that often occurs in mergers. Therefore, we will use only the compressed APV approach in the following section to illustrate valuing a target and setting the bid price.

[9]See Chapter 7 for an explanation of market multiple analysis.

SELF-TEST

What are the two questions that an acquirer must answer?

What are four methods for estimating a target's value?

22-7 Estimating a Target's Value

Caldwell Inc., a large technology company, is evaluating the potential acquisition of a smaller company, Tutwiler Controls. (Tutwiler is the same company examined in Chapter 21.) If the acquisition takes place, it will occur on January 1, 2017, and so the valuation will be as of that date and will be based on the capital structure and synergies expected after the acquisition. Tutwiler currently has a $62.5 million market value of equity and $27 million in debt, for a total market value of $89.5 million. Thus, Tutwiler's capital structure consists of $\$27/(\$62.5 + \$27) = 30.17\%$ debt. Caldwell intends to finance the acquisition with this same proportion of debt and plans to maintain this constant capital structure throughout the projection period and thereafter (although Caldwell will explore a different financing plan in a later section). Tutwiler is a publicly traded company, and its market-determined pre-merger beta was 1.2. Given a risk-free rate of 7% and a 5% market risk premium, the Capital Asset Pricing Model produces a pre-merger required rate of return on equity, r_{sL}, of:

$$\begin{aligned} r_{sL} &= r_{RF} + b(RP_M) \\ &= 7\% + 1.2(5\%) = 13\% \end{aligned}$$

Tutwiler's cost of debt is 9% and it is in the 40% federal-plus-state tax bracket. Its WACC is:

$$\begin{aligned} WACC &= w_d(1 - T)r_d + w_s r_{sL} \\ &= 0.3017(0.60)(9\%) + 0.6983(13\%) \\ &= 10.707\% \end{aligned}$$

How much would Tutwiler be worth to Caldwell after the merger? The following sections answer this question.

22-7a Projecting Post-Merger Cash Flows

resource

*See **Ch22 Tool Kit.xlsx** for details.*

The first order of business is to estimate the post-merger cash flows that Tutwiler will produce. This is by far the most important task in any merger analysis. In a **pure financial merger**, defined as one in which no operating synergies are expected, the incremental post-merger cash flows are simply the target firm's expected cash flows. In an **operating merger**, in which the two firms' operations are to be integrated, forecasting future cash flows is obviously more difficult, because potential synergies must be estimated. People from marketing, production, human resources, and accounting play leading roles here, with financial managers focusing on financing the acquisition and performing an analysis designed to determine whether the projected cash flows are worth the cost.

In this chapter, we take the projections as given and concentrate on how they are analyzed. Using the same techniques explained in ***Web Extension 21A***, we have created post-merger projections for Tutwiler, taking into account all expected synergies and maintaining a constant capital structure; see the file ***Ch22 Tool Kit.xlsx***. Both Caldwell and Tutwiler are in the 40% marginal federal-plus-state tax bracket. The cost of debt after the acquisition will remain at 9%. The projections assume that growth in the post-horizon period will be 6% due to synergies. Table 22-2 shows these projections (keep in mind that these projections differ from those of Chapter 21 because they reflect the synergies expected in the acquisition).

TABLE 22-2
Post-Merger Projections for the Tutwiler Subsidiary (Millions of Dollars)

	1/1/17	12/31/17	12/31/18	12/31/19	12/31/20	12/31/21
Panel A: Selected Items from Projected Financial Statements						
1. Net sales		$105.0	$126.0	$151.0	$174.0	$191.0
2. Cost of goods sold		80.0	94.0	113.0	129.3	142.0
3. Selling and administrative expenses		10.0	12.0	13.0	15.0	16.0
4. Depreciation		8.0	8.0	9.0	9.0	10.0
5. EBIT		$ 7.0	$ 12.0	$ 16.0	$ 20.7	$ 23.0
6. Interest expense[a]		3.0	3.2	3.5	3.7	3.9
7. Debt[b]	$ 33.2	35.8	38.7	41.1	43.6	46.2
8. Total net operating capital	116.0	117.0	121.0	125.0	131.0	138.0
Panel B: Compressed APV Model Cash Flows						
9. NOPAT = EBIT(1 − T)[c]		$ 4.2	$ 7.2	$ 9.6	$ 12.4	$ 13.8
10. Less net investment in operating capital		1.0	4.0	4.0	6.0	7.0
11. Free cash flow		$ 3.2	$ 3.2	$ 5.6	$ 6.4	$ 6.8
12. Interest tax saving = Interest(T)[c]		$ 1.2	$ 1.3	$ 1.4	$ 1.5	$ 1.6

Source: See the file ***Ch21 Tool Kit.xlsx***. Numbers are reported as rounded values for clarity, but are calculated using *Excel*'s full precision. Thus, intermediate calculations using the figure's rounded values will be inexact.

Notes:

[a] Interest payments are based on Tutwiler's existing debt, new debt to be issued to finance the acquisition, and additional debt required to finance annual growth.

[b] Debt is existing debt plus additional debt required to maintain a constant capital structure. Caldwell will increase Tutwiler's debt by $6.2 million, from $27 million to $33.2 million, at the time of the acquisition in order to keep the capital structure constant. This increase occurs because the post-merger synergies make Tutwiler more valuable to Caldwell than it was on a stand-alone basis. Therefore, it can support more dollars of debt and still maintain the constant debt ratio.

[c] The tax rate is 40%.

Panel A of Table 22-2 shows selected items from the projected financial statements. Panel B shows the calculations for free cash flow and the annual tax savings due to the deductibility of interest.

Of course, the post-merger cash flows are extremely difficult to estimate, and in merger valuations—just as in capital budgeting analysis—sensitivity, scenario, and simulation analyses should be conducted.[11] Indeed, in a friendly merger the acquiring firm would send a team consisting of literally dozens of financial analysts, accountants, engineers, and so forth to the target firm's headquarters. They would go over its books, estimate required maintenance expenditures, set values on assets such as real estate and petroleum reserves, and the like. Such an investigation, which is one example of **due diligence**, is an essential part of any merger analysis.

Following is the valuation of Tutwiler.

[11] We purposely kept the cash flows simple in order to focus on key analytical issues. In actual merger valuations, the cash flows would be much more complex, normally including such items as tax loss carryforwards, tax effects of plant and equipment valuation adjustments, and cash flows from the sale of some of the subsidiary's assets.

22-7b Valuation Using the Compressed APV Approach

resource

*See **Ch22 Tool Kit.xlsx** on the textbook's Web site for all calculations. Note that rounded intermediate values are shown in the text, but all calculations are performed in Excel using nonrounded values.*

The compressed APV approach requires an estimate of Tutwiler's unlevered cost of equity. As shown in Chapter 21, the levered cost of equity is:

$$r_{sL} = r_{sU} + (r_{sU} - r_d)(w_d/w_s) \quad \textbf{(22-1)}$$

Inputting Tutwiler's capital structure, cost of equity, and cost of debt, Equation 22-1 can be rearranged to estimate the unlevered cost of equity:

$$r_{sU} = w_s r_{sL} + w_d r_d \quad \textbf{(22-1a)}$$

$$= 0.6983(13\%) + 0.3017(9\%)$$
$$= 11.793\%$$

In other words, if Tutwiler had no debt, its cost of equity would be 11.793%.[12]

Instead of directly estimating the unlevered cost of equity, we can estimate the unlevered beta, b_U, and then calculate the unlevered cost of equity. Chapter 21 shows an expression for the unlevered beta:

$$b = b_U + (b_U - b_d)(w_d/w_s) \quad \textbf{(22-2)}$$

where b_d is the beta of the debt.

To estimate the beta on debt due to systematic risk, we can start with the observed cost of debt and solve the CAPM for the implied beta on debt:

$$b_d = (r_d - r_{RF})/RP_M$$
$$= (0.09 - 0.07)/0.05$$
$$= 0.4$$

Rearranging Equation 22-2, Tutwiler's unlevered beta is:

$$b_U = [b + b_d(w_d/w_s)]/[1 + (w_d/w_s)]$$
$$= [1.2 + 0.4(0.3017/0.6983)]/[1 + (0.3017/0.6983)]$$
$$= 0.9586$$

Using the CAPM, the unlevered cost of equity is:

$$r_{sU} = r_{RF} + b_U(RP_M)$$
$$= 7\% + 0.9586(5\%) = 11.79\%$$

This is exactly the same value previously estimated. Because this alternative approach requires that we assume the CAPM is the correct model, and because it takes extra steps, we usually use the first method shown in Equations 22-1 and 22-1a.

[12]Notice that we do not use the Hamada equation to lever or unlever beta to determine the required return on equity because the Hamada equation assumes zero growth. Instead, we use Equation 22-1a to determine the unlevered cost of equity, which assumes that the growing debt tax shield is discounted at the unlevered cost of equity.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The horizon value of Tutwiler's unlevered cash flows ($HV_{U,2021}$) and tax shield ($HV_{TS,2021}$) can be calculated using the constant growth formula with the unlevered cost of equity as the discount rate, as shown in Chapter 21:[13]

$$HV_{U,2021} = \frac{FCF_{2022}}{r_{sU} - g_L} = \frac{FCF_{2021}(1 + g_L)}{r_{sU} - g_L} = \frac{\$6.800(1.06)}{0.11793 - 0.06} = \$124.4 \text{ million}$$

$$HV_{TS,2021} = \frac{TS_{2022}}{r_{sU} - g_L} = \frac{TS_{2021}(1 + g_L)}{r_{sU} - g_L} = \frac{\$1.57(1.06)}{0.11793 - 0.06} = \$28.7 \text{ million}$$

The sum of the two horizon values is $\$124.4 + \$28.7 = \$153.1$ million. This is the horizon value of operations.

Row 11 in Table 22-2 shows the projected free cash flows. The unlevered value of operations is calculated as the present value of the free cash flows during the forecast period and the horizon value of the free cash flows:

$$\begin{aligned} V_{Unlevered} &= \frac{\$3.2}{(1 + 0.11793)^1} + \frac{\$3.2}{(1 + 0.11793)^2} + \frac{\$5.6}{(1 + 0.11793)^3} \\ &\quad + \frac{\$6.4}{(1 + 0.11793)^4} + \frac{\$6.8 + \$124.4}{(1 + 0.11793)^5} \\ &= \$88.7 \text{ million} \end{aligned}$$

This shows that Tutwiler's operations would be worth \$88.7 million if it had no debt.

resource

*See **Ch22 Tool Kit.xlsx** on the textbook's Web site for all calculations. Note that rounded intermediate values are shown in the text, but all calculations are performed in* Excel *using nonrounded values.*

Row 12 shows the yearly interest tax savings. The value of the tax shield is calculated as the present value of the yearly tax savings and the horizon value of the tax shield:

$$\begin{aligned} V_{Tax\ shield} &= \frac{\$1.2}{(1 + 0.11793)^1} + \frac{\$1.3}{(1 + 0.11793)^2} + \frac{\$1.4}{(1 + 0.11793)^3} \\ &\quad + \frac{\$1.5}{(1 + 0.11793)^4} + \frac{\$1.57 + \$28.7}{(1 + 0.11793)^5} \\ &= \$21.4 \text{ million} \end{aligned}$$

Thus, Tutwiler's operations would be worth only \$88.7 million if it had no debt, but its capital structure contributes \$21.4 million in value due to the tax deductibility of its interest payments. Because Tutwiler has no nonoperating assets, the total value of the firm is the sum of the unlevered value of operations, \$88.7 million, and the value of the tax shield, \$21.4 million, for a total of \$110.1 million. The value of the equity is equal to this total value less Tutwiler's outstanding debt of \$27 million: $\$110.1 - \$27 = \$83.1$ million.

SELF-TEST

Why is the adjusted present value approach appropriate for situations with a changing capital structure?

Describe the steps required to apply the APV approach.

[13]Note that we show two decimal places for the 2021 tax shield even though Table 22-2 reports only one decimal place. All calculations are performed in *Excel*, which uses the full nonrounded values.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

22-8 Setting the Bid Price

Under the acquisition plan, Caldwell would assume Tutwiler's debt and would also take on additional short-term debt as necessary to complete the purchase. The valuation model shows that $83.1 million is the most it should pay for Tutwiler's stock. If it paid more, then Caldwell's own value would be diluted. On the other hand, if it could get Tutwiler for less than $83.1 million, Caldwell's stockholders would gain value. Therefore, Caldwell should bid something less than $83.1 million when it makes an offer for Tutwiler.

Now consider the target company. As stated earlier, Tutwiler's value of equity as an independent operating company is $62.5 million. If Tutwiler were acquired at a price greater than $62.5 million, then its stockholders would gain value, whereas they would lose value at any lower price.

The difference between $62.5 million and $83.1 million, or $20.6 million, represents **synergistic benefits** expected from the merger. If there were no synergistic benefits, the maximum bid would be the current value of the target company. The greater the synergistic gains, the greater the gap between the target's current price and the maximum the acquiring company could pay.

The issue of how to divide the synergistic benefits is critically important. Obviously, both parties would want to get the best deal possible. In our example, if it knew the maximum price Caldwell could pay, Tutwiler's management would argue for a price close to $83.1 million. Caldwell, on the other hand, would try to get Tutwiler at a price as close to $62.5 million as possible.

Where, within the range of $62.5 to $83.1 million, will the actual price be set? The answer depends on a number of factors, including whether Caldwell offers to pay with cash or securities, the negotiating skills of the two management teams, and, most importantly, the bargaining positions of the two parties as determined by fundamental economic conditions. Let's first consider bargaining power and then examine the mechanics of a cash offer versus a stock offer.

22-8a Relative Bargaining Power

To illustrate the relative bargaining power of the target and the acquirer, assume there are many companies similar to Tutwiler that Caldwell could acquire, but suppose that no company other than Caldwell could gain synergies by acquiring Tutwiler. In this case, Caldwell would probably make a relatively low, take-it-or-leave-it offer, and Tutwiler would probably take it because some gain is better than none. On the other hand, if Tutwiler has some unique technology or other asset that many companies want, then once Caldwell announces its offer, others would probably make competing bids and the final price would probably be close to (or even above) $83.1 million. A price above $83.1 million presumably would be paid by some other company with a better synergistic fit or with a management that is more optimistic about Tutwiler's cash flow potential.

Caldwell would, of course, want to keep its maximum bid secret, and it would plan its bidding strategy carefully. If Caldwell thought other bidders would emerge or that Tutwiler's management might resist in order to preserve their jobs, Caldwell might make a high preemptive bid in hopes of scaring off competing bids or management resistance. On the other hand, it might make a lowball bid in hopes of "stealing" the company.[14]

[14]For an interesting discussion of the aftereffects of losing a bidding contest, see Mark L. Mitchell and Kenneth Lehn, "Do Bad Bidders Become Good Targets?" *Journal of Applied Corporate Finance*, Summer 1990, pp. 60–69.

22-8b Cash Offers versus Stock Offers

Most target stockholders prefer to sell their shares for cash rather than to exchange them for stock in the post-merger company. Following is a brief description of each payment method.

CASH OFFERS

Tutwiler's pre-merger equity is worth \$62.5 million. With 10 million shares outstanding, Tutwiler's stock price is \$62.5/10 = \$6.25. If the synergies are realized, then Tutwiler's equity will be worth \$83.1 million to Caldwell, so \$83.1/10 = \$8.31 is the maximum price per share that Caldwell should be willing to pay to Tutwiler's stockholders. For example, Caldwell might offer \$7.75 cash for each share of Tutwiler stock.

STOCK OFFERS

In a stock offer, Tutwiler's stockholders exchange their Tutwiler shares for new shares in the post-merger company, which will be named Caldwell-Tutwiler. Targets typically prefer cash offers to stock offers, all else equal, but taxation of the offer prevents all else from being equal. We discuss taxation in more detail in Section 22-10, but for now you should know that stock offerings are taxed more favorably than cash offerings. In this case, perhaps Caldwell should offer a package worth \$7.50 per share. With 10 million outstanding Tutwiler shares, the Tutwiler shareholders must end up owning \$7.50 × 10 million = \$75 million worth of stock in the post-merger company.

Suppose Caldwell has 20 million shares of stock outstanding (n_{Old}) prior to the merger and the stock price per share is \$15. Then the total pre-merger value of Caldwell's equity is \$15 × 20 million = \$300 million. As calculated previously, the post-merger value of Tutwiler to Caldwell is \$83.1 million. Therefore, the total post-merger value of Caldwell-Tutwiler will be \$300 + \$83.1 = \$383.1 million.

After the merger, Tutwiler's former stockholders should own \$75/\$383.1 = 0.196 = 19.58% of the post-merger Caldwell-Tutwiler. With 20 million Caldwell shares outstanding, Caldwell must issue enough new shares, n_{New}, to the Tutwiler stockholders (in exchange for the Tutwiler shares) so that Tutwiler's former stockholders will own 19.6% of the shares of Caldwell-Tutwiler:

$$\text{Percent required by target stockholders} = \frac{n_{New}}{n_{New} + n_{Old}}$$

$$19.58\% = \frac{n_{New}}{n_{New} + 20}$$

$$n_{New} = \frac{20 \times 0.1958}{1 - 0.1958} = 4.87 \text{ million}$$

Tutwiler's former stockholders will exchange 10 million shares of stock in Tutwiler for 4.87 million shares of stock in the combined Caldwell-Tutwiler. Thus, the exchange ratio is 4.87/10 = 0.487.

After the merger, there will be 4.87 million new shares for a total of 24.87 million shares. With a combined intrinsic equity value of \$383.1 million, the resulting price per share will be \$383.1/24.87 = \$15.40. The total value owned by Tutwiler's shareholders is this price multiplied by their shares: \$15.40 × 4.87 million = \$75 million. Also notice that the price will increase from \$15.00 per share before the merger to \$15.40 after the merger, so the merger will benefit Caldwell's shareholders if the synergies are realized.

22-9 Analysis When the Capital Structure Changes during the Explicit Forecast Period

Tutwiler currently has equity worth $62.5 million and debt of $27 million, giving it a capital structure financed with about 30% debt: $\$27.0/(\$62.5 + \$27.0) = 0.302 = 30.2\%$. Suppose Caldwell has decided to increase Tutwiler's debt from 30% to 50% over the next 5 years and to maintain the capital structure at that level for 2021 and thereafter. How would this affect Tutwiler's valuation? The free cash flows will not change, but the interest tax shield, the WACC, and the bid price will all change. At a 30% debt level, the interest rate on Tutwiler's debt was 9%. However, at a 50% debt level, Tutwiler is more risky, and its interest rate would rise to 9.5% to reflect this additional risk. Because the capital structure is changing, we use the APV for this analysis.

22-9a The Effect on the Tax Shield

It is reasonable to assume that Caldwell will use more debt during the first 5 years of the acquisition if its long-run target capital structure is 50% debt. With more debt and a higher interest rate, the interest payments will be higher than those shown in Table 22-2, thus increasing the tax savings. The interest payments and tax savings with more debt and a higher interest rate are projected as follows:

resource

*For more information on projecting financial statements, see **Web Extension 21A** and **Ch21 Tool Kit.xlsx** on the textbook's Web site.*

	2017	2018	2019	2020	2021
Interest	$5.00	$6.00	$7.00	$7.50	$8.30
Interest tax savings	2.00	2.40	2.80	3.00	3.32

In these projections, Tutwiler will reach its target capital structure of 50% debt and 50% equity by the start of 2021.[15]

22-9b The Effect on the Bid Price

The new capital structure would affect the maximum bid price by changing the value of Tutwiler to Caldwell. Based on the new tax shields, the unlevered and tax shield horizon values in 2021 are calculated as:

$$HV_{U,2021} = \frac{FCF_{2022}}{r_{sU} - g} = \frac{FCF_{2021}(1+g)}{r_{sU} - g} = \frac{\$6.800(1.06)}{0.11793 - 0.06} = \$124.4$$

$$HV_{TS,2021} = \frac{TS_{2022}}{r_{sU} - g} = \frac{TS_{2021}(1+g)}{r_{sU} - g} = \frac{\$3.32(1.06)}{0.11793 - 0.06} = \$60.7$$

[15]The last year's projected interest expense must be consistent with the assumed capital structure in order to use the relation $TS_{N+1} = TS_N(1 + g_L)$ in calculating the tax shield horizon value.

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Based on the new interest payments and horizon values, the cash flows to be discounted at the unlevered cost of equity are as follows:

	2017	2018	2019	2020	2021
Free cash flow	$3.2	$3.2	$5.6	$6.4	$ 6.8
Unlevered horizon value					124.4
FCF plus horizon value	$3.2	$3.2	$5.6	$6.4	$131.2
Interest tax saving	2.0	2.4	2.8	3.0	3.3
Tax shield horizon value					$ 60.7
TS_t plus horizon value	$2.0	$2.4	$2.8	$3.0	$ 64.0

The present value of the free cash flows and their horizon value is $88.7 million, just as it was under the 30% debt policy; the unlevered value of operations is not impacted by the change in capital structure:

$$\begin{aligned} V_{\text{Unlevered}} &= \frac{\$3.2}{(1+0.11793)^1} + \frac{\$3.2}{(1+0.11793)^2} + \frac{\$5.6}{(1+0.11793)^3} \\ &\quad + \frac{\$6.4}{(1+0.11793)^4} + \frac{\$6.8+\$124.4}{(1+0.11793)^5} \\ &= \$88.7 \text{ million} \end{aligned}$$

The present value of the tax shields and their horizon value is $44.3 million, which is $22.9 million more than the value of the tax shield under the 30% debt policy:

$$\begin{aligned} V_{\text{Tax shield}} &= \frac{\$2.0}{(1+0.11793)^1} + \frac{\$2.4}{(1+0.11793)^2} + \frac{\$2.8}{(1+0.11793)^3} \\ &\quad + \frac{\$3.0}{(1+0.11793)^4} + \frac{\$3.3+\$60.7}{(1+0.11793)^5} \\ &= \$44.3 \text{ million} \end{aligned}$$

Thus, Tutwiler is worth almost $23 million more to Caldwell if it is financed with 50% rather than 30% debt because of the added value of the tax shields.

The value of operations under the new 50% debt policy is the sum of the unlevered value of operations and the value of the tax shields, or $133.0 million. There are no nonoperating assets to add, and subtracting the debt of $27 million leaves the value of Tutwiler's equity at $106.0 million. Because Tutwiler has 10 million shares outstanding, the maximum amount Caldwell should be willing to pay per share, given a post-merger target capital structure of 50% debt, is $10.60. This is more than the $8.31 maximum price if the capital structure had 30% debt. The difference, $2.29 per share, reflects the added value of the interest tax shields under the higher-debt plan.

SELF-TEST

How does a change in capital structure affect the valuation analysis?

22-10 Taxes and the Structure of the Takeover Bid

In a merger, the acquiring firm can either buy the target's assets or buy shares of stock directly from the target's shareholders. If the offer is for the target's assets, then the target's board of directors will make a recommendation to the shareholders, who will vote

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. either to accept or reject the offer. If they accept the offer, the payment goes directly to the target corporation, which pays off any debt not assumed by the acquiring firm, pays any corporate taxes that are due, and then distributes the remainder of the payment to the shareholders, often in the form of a liquidating dividend. In this situation, the target firm is usually dissolved and no longer continues to exist as a separate legal entity, although its assets and workforce may continue to function as a division or as a wholly owned subsidiary of the acquiring firm. The acquisition of assets is a common form of takeover for small and medium-sized firms, especially those that are not publicly traded. A major advantage of this method compared with the acquisition of the target's stock is that the acquiring firm simply acquires assets and is not saddled with any hidden liabilities. In contrast, if the acquiring firm buys the target's stock, then it is responsible for any legal contingencies against the target, even for those that might have occurred prior to the takeover.

An offer for a target's stock rather than its assets can be made either directly to the shareholders, as is typical in a hostile takeover, or indirectly through the board of directors, which in a friendly deal makes a recommendation to the shareholders to accept the offer. In a successful offer, the acquiring firm will end up owning a controlling interest or perhaps even all of the target's stock. Sometimes the target retains its identity as a separate legal entity and is operated as a subsidiary of the acquiring firm, and sometimes its corporate status is dissolved and it is operated as one of the acquiring firm's divisions.

The payment offered by the acquiring firm can be in the form of cash, stock of the acquiring firm, debt of the acquiring firm, or some combination. The structure of the bid affects: (1) the capital structure of the post-merger firm, (2) the tax treatment of both the acquiring firm and the target's stockholders, (3) the ability of the target firm's stockholders to benefit from future merger-related gains, and (4) the types of federal and state regulations to which the acquiring firm will be subjected.

The tax consequences of the merger depend on whether it is classified as a *taxable offer* or a *nontaxable offer*.[16] In general, a nontaxable offer is one in which the form of payment is predominately stock, although the application of this simple principle is much more complicated in practice. The Internal Revenue Code views a mostly stock merger as an exchange rather than a sale, making it a nontaxable event. However, if the offer includes a significant amount of cash or bonds, then the IRS views it as a sale, and it is a taxable transaction just like any other sale.

In a nontaxable deal, target shareholders who receive shares of the acquiring company's stock do not have to pay any taxes at the time of the merger. When they eventually sell their stock in the acquiring company, they must pay a tax on the gain. The amount of the gain is the sales price of their stock in the acquiring company minus the price at which they purchased their original stock in the target company.[17] In a taxable offer, the gain between the offer price and the original purchase price of the target stock is taxed in the year of the merger.[18]

All other things equal, stockholders prefer nontaxable offers, because they may then postpone taxes on their gains. Furthermore, if the target firm's stockholders receive stock, they will benefit from any synergistic gains produced by the merger. Most target

[16]For more details, see J. Fred Weston, Mark L. Mitchell, and Harold Mulherin, *Takeovers, Restructuring, and Corporate Governance*, 4th ed. (Upper Saddle River, NJ: Prentice-Hall, 2004), especially Chapter 4. Also see Kenneth E. Anderson, Thomas R. Pope, and John L. Kramer, eds., *Prentice Hall's Federal Taxation 2015: Corporations, Partnerships, Estates, and Trusts*, 28th ed. (Upper Saddle River, NJ: Prentice-Hall, 2013), especially Chapter 7.

[17]This is a capital gain if it has been at least 1 year since they purchased their original stock in the target.

[18]Even in nontaxable deals, taxes must be paid in the year of the merger by any stockholders who receive cash.

Tempest in a Teapot?

In 2001, amid a flurry of warnings and lobbying, the Financial Accounting Standards Board (FASB) in its Statement 141 eliminated the use of pooling for merger accounting, requiring that purchase accounting be used instead. Because the change would otherwise have required that all purchased goodwill be amortized and reported earnings be reduced, the FASB also issued Statement 142, which eliminated the regular amortization of purchased goodwill, replacing it with an "impairment test." The impairment test requires that companies evaluate annually their purchased goodwill and write it down if its value has declined. This impairment test resulted in Time Warner's unprecedented 2002 write-down of $54 billion of goodwill associated with the AOL merger.

So what exactly is the effect of the change? First and foremost, the change does *nothing* to the firm's actual cash flows. Purchased goodwill may still be amortized for federal income tax purposes, so the change does not affect the actual taxes a company pays, nor does it affect the company's operating cash flows. However, it does affect the earnings that companies report to their shareholders. Firms that used to have large goodwill charges from past acquisitions have seen their reported earnings increase because they no longer have to amortize the remaining goodwill. Firms whose acquisitions have fared badly, such as Time Warner, must make large write-downs. Executives facing boosted earnings hope—and executives facing a write-down fear—that investors will not see through these accounting changes. However, evidence suggests that investors realize that a company's assets have deteriorated long before the write-down actually occurs, and they build this information into the price of the stock. For example, Time Warner's announcement of its $54 billion charge in January 2002 resulted in only a blip in its stock price at that time, even though the write-down totaled more than a third of its market value. The market had recognized the decline in value months earlier, and by the time of the announcement Time Warner had already lost more than $100 billion in market value.

shareholders are thus willing to give up their stock for a lower price in a nontaxable offer than in a taxable one. As a result, one might expect nontaxable bids to dominate. However, this is not the case: Roughly half of all mergers have been taxable. The reason for this is explained in the following paragraphs.

The form of the payment also has tax consequences for the acquiring and target firms. To illustrate, consider the following situation. The target firm has assets with a book value of $100 million, but these assets have an appraised value of $150 million. The offer by the acquiring firm is worth $225 million. If it is a nontaxable offer, then after the merger the acquiring firm simply adds the $100 million book value of the target's assets to its own assets and continues to depreciate them according to their previous depreciation schedules. To keep the example simple, we assume the target has no debt.

The situation is more complicated for a taxable offer, and the treatment is different depending on whether the offer is for the target's assets or for its stock. If the acquiring firm offers $225 million for the target's assets, then the target firm must pay a tax on the gain of $\$225 - \$100 = \$125$ million. Assuming a corporate tax rate of 40%, this tax is $0.40(\$125) = \$50$ million. This leaves the target with $\$225 - \$50 = \$175$ million to distribute to its shareholders upon liquidation. Adding insult to injury, the target's shareholders must also pay individual taxes on any of their own gains.[19] This is truly a taxable transaction, with taxes assessed at both the corporate and individual levels!

In contrast to the tax disadvantages for the target and its shareholders, the acquiring firm receives two major tax advantages. First, it records the acquired assets at their appraised value and depreciates them accordingly. Thus, it will depreciate $150 million

[19]Our example assumes that the target is a publicly owned firm, which means that it must be a "C corporation" for tax purposes. However, if it is privately held then it might be an "S corporation," in which case only the stockholders would be taxed. This helps smaller firms to use mergers as an exit strategy.

of assets in this taxable transaction versus only $100 million in a nontaxable transaction. Second, it will create $75 million in a new asset account called **goodwill**, which is the difference between the purchase price of $225 million and the appraised value of $150 million. Tax laws that took effect in 1993 permit companies to amortize this goodwill over 15 years using the straight-line method and also to deduct the amortization from taxable income. The net effect is that the full purchase price of $225 million can be written off in a taxable merger versus only the original book value of $100 million in a nontaxable transaction.

Now suppose the acquiring firm offers $225 million for the target's stock, rather than just its assets as in the preceding example, in a taxable offer. After completing the merger, the acquiring firm must choose between two tax treatments. Under the first alternative, it will record the assets at their book value of $100 million and continue depreciating them using their current schedules. This treatment does not create any goodwill. Under the second alternative, it will record the assets at their appraised value of $150 million and create $75 million of goodwill. As described earlier for the asset purchase, this allows the acquiring firm to effectively depreciate the entire purchase price of $225 million for tax purposes. However, there will also be an immediate tax liability on the $125 million gain, just as when the firm purchased assets.[20] Therefore, many companies choose not to mark up the assets. Figure 22-1 illustrates the tax implications for the various types of transactions.

If you think this is complicated, you are right! At this point, you should know enough to talk with specialized accountants and lawyers or be ready to delve into tax accounting texts, but merger taxation is too complex a subject to be covered thoroughly in a general finance textbook.

Securities laws also have an effect on the offer's construction. The SEC has oversight over the issuance of new securities, including stock or debt issued in connection with a merger. Therefore, whenever a corporation bids for control of another firm through the exchange of equity or debt, the entire process must take place under the scrutiny of the Securities and Exchange Commission. The time required for such reviews allows target managements to implement defensive tactics and other firms to make competing offers; as a result, nearly all hostile tender offers are for cash rather than securities.

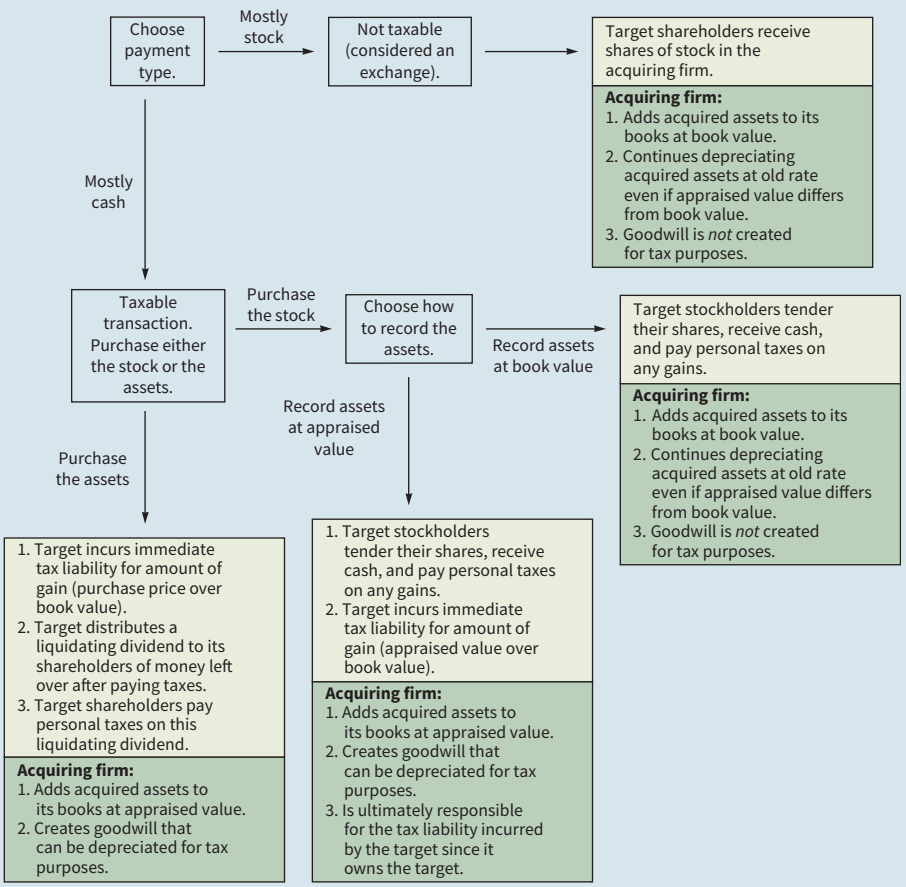
SELF-TEST

What are some alternative ways of structuring takeover bids?

How do taxes influence the payment structure?

How do securities laws affect the payment structure?

22-11 Financial Reporting for Mergers



Although a detailed discussion of financial reporting is best left to accounting courses, the accounting implications of mergers cannot be ignored. Currently, mergers are handled using **purchase accounting**.[21] Keep in mind, however, that all large companies are required to keep two sets of books. The first is for the IRS, and it reflects the tax treatment of mergers as described in the previous section. The second is for financial reporting, and

[20]Technically speaking, it is the target firm that is responsible for this tax on the write-up. Keep in mind, however, that the acquiring firm previously purchased the stock in the target and so, in reality, must bear the brunt of the tax.

[21]Recall that in 2001, the Financial Accounting Standards Board (FASB) issued Statement 141, which eliminated the use of *pooling* accounting.

FIGURE 22-1
Merger Tax Effects

Note:
These are actual cash tax effects. However, the tax effects reported to shareholders will be different because shareholder statements must conform to GAAP conventions, not to federal Tax Code conventions. For example, purchased goodwill can no longer be deducted for shareholder reporting under GAAP, even though it is still deductible for federal tax purposes. See the box titled "Tempest in a Teapot?" which deals with changes in the accounting treatment of mergers and goodwill.

it reflects the treatment described here. As you will see, the rules for financial reporting differ from those for the IRS.

22-11a Purchase Accounting

Table 22-3 illustrates purchase accounting. Here, Firm A is assumed to have "bought" Firm B using the stock of the acquiring company. If the price paid is exactly equal to the acquired firm's *net asset value*, which is defined as its total assets minus its liabilities, then the consolidated balance sheet will be as if the two statements were merged. Normally, though, there is an important difference. If the price paid *exceeds* the net asset value, then asset values will be increased to reflect the price actually paid, whereas if the price paid is *less* than the net asset value, then assets must be written down when preparing the consolidated balance sheet.

TABLE 22-3
Accounting for Mergers: Firm A Acquires Firm B with Stock

			Post-Merger: Firm A		
	Firm A (1)	**Firm B** (2)	**$20 Paid**[a] (3)	**$30 Paid**[a] (4)	**$50 Paid**[a] (5)
Current assets	$ 50	$25	$ 75	$ 75	$ 80[b]
Fixed assets	50	25	65[c]	75	80[b]
Goodwill[d]	0	0	0	0	10[d]
Total assets	$100	$50	$140	$ 150	$ 170
Liabilities	$ 40	$20	$ 60	$ 60	$ 60
Equity	60	30	80[e]	90	110[f]
Total claims	$100	$50	$140	$150	$170

Notes:

[a] The price paid is the *net asset value*—that is, total assets minus liabilities.

[b] Here we assume that Firm B's current and fixed assets are both increased to $30.

[c] Here we assume that Firm B's fixed assets are written down from $25 to $15 before constructing the consolidated balance sheet.

[d] *Goodwill* refers to the excess paid for a firm above the appraised value of the physical assets purchased. Goodwill represents payment both for intangibles such as patents and for "organization value," such as that associated with having an effective sales force. Beginning in 2001, purchased goodwill such as this may not be amortized for financial statement reporting purposes.

[e] Firm B's common equity is reduced by $10 prior to consolidation to reflect the fixed asset write-off.

[f] Firm B's equity is increased to $50 to reflect the above-book purchase price.

Note that Firm B's net asset value is $30, which is also its reported common equity value. This $30 book value could be equal to the market value (which is determined by investors based on the firm's earning power), but book value could also be more or less than the market value. Three situations are considered in Table 22-4. First, in Column 3 we assume that Firm A gives stock worth $20 for Firm B. Thus, B's assets as reported on its balance sheet were overvalued, and A pays less than B's net asset value. The overvaluation could be in either fixed or current assets; an appraisal would be made, but we assume it is fixed assets that are overvalued. Accordingly, we reduce B's fixed assets and also its common equity by $10 before constructing the consolidated balance sheet shown in Column 3. Next, in Column 4, we assume that A pays exactly the net asset value for B. In this case, the financial statements are simply combined.

Finally, in Column 5 we assume that A pays more than the net asset value for B: $50 is paid for $30 of net assets. This excess is assumed to be partly attributable to undervalued assets (land, buildings, machinery, and inventories) and so, to reflect this undervaluation, current and fixed assets are each increased by $5. In addition, we assume that $10 of the $20 excess of market value over book value is due to a superior sales organization or to some other intangible factor, and we post this excess as goodwill. Firm B's common equity is increased by $20, the sum of the increases in current and fixed assets plus goodwill, and this markup is also reflected in Firm A's post-merger equity account.[22]

[22]This example assumes that additional debt was not issued to help finance the acquisition. If the acquisition were totally debt financed, then the post-merger balance sheet would show an increase in debt rather than an increase in the equity account. If it were financed by a mix of debt and equity, both accounts would increase. If the acquisition were paid for with cash on hand, then current assets would decrease by the amount paid and the equity account would not increase.

TABLE 22-4
Income Statement Effects

	Pre-Merger		Post-Merger: Firm A
	Firm A (1)	Firm B (2)	Merged (3)
Sales	$100.0	$ 50.0	$150.0
Operating costs	72.0	36.0	109.0[a]
Operating income	$ 28.0	$14.0	$ 41.0[a]
Interest (10%)	4.0	2.0	6.0
Taxable income	$ 24.0	$ 12.0	$ 35.0
Taxes (40%)	9.6	4.8	14.0
Net income	$ 14.4	$ 7.2	$ 21.0
EPS[b]	$ 2.40	$ 2.40	$ 2.33

Notes:

[a] Operating costs are $1 higher than they otherwise would be; this reflects the higher reported costs (depreciation and cost of goods sold) caused by the physical asset markup at the time of purchase.

[b] Before the merger, Firm A had six shares and Firm B had three shares. Firm A gives one of its shares for each of Firm B's, so A has nine shares outstanding after the merger.

22-11b Income Statement Effects

A merger can have a significant effect on reported profits. If asset values are increased, as they often are under a purchase, then this must be reflected in higher depreciation charges (and also in a higher cost of goods sold if inventories are written up). This, in turn, will further reduce reported profits. Prior to 2001, goodwill was also amortized over its expected life. Now, however, goodwill is subject to an "annual impairment test." If the fair market value of the goodwill has declined over the year, then the amount of the decline must be charged to earnings. If not, then there is no charge, but gains in goodwill cannot be added to earnings.

resource

*See **Ch22Tool Kit.xlsx** on the textbook's Web site for details.*

Table 22-4 illustrates the income statement effects of the write-up of current and fixed assets. We assume A purchased B for $50, creating $10 of goodwill and $10 of higher physical asset value. As Column 3 indicates, the asset markups cause reported profits to be lower than the sum of the individual companies' reported profits.

The asset markup is also reflected in earnings per share. In our hypothetical merger, we assume that nine shares exist in the consolidated firm. (Six of these shares went to A's stockholders, and three went to B's.) The merged company's EPS is $2.33, whereas each of the individual companies' EPS was $2.40.

SELF-TEST

What is purchase accounting for mergers?

What is goodwill? What impact does goodwill have on the firm's balance sheet? On its income statement?

22-12 Analysis for a "True Consolidation"

Most of our analysis in the preceding sections assumed that one firm plans to acquire another. However, in many situations it is hard to identify an "acquirer" and a "target"—the merger appears to be a true "merger of equals," as was the case with the Exxon–Mobil and First Union–Wachovia mergers. In such cases, how is the analysis handled?

The first step is to estimate the value of the combined enterprise, incorporating any synergies, tax effects, or capital structure changes. The second step is to decide how to allocate the new company's stock between the two sets of old stockholders. Because of synergy, one would normally expect the consolidated value to exceed the sum of the pre-announcement values of the two companies. For example, Company A might have had a pre-merger equity value of $10 billion, found as (Number of shares)(Price per share), and Company B might have had a pre-merger value of $15 billion. If the post-merger value of new Company AB is estimated to be $30 billion, then that value must be allocated. Company A's stockholders must receive enough shares to give them a projected value of at least $10 billion, and Company B's stockholders must receive at least $15 billion. But how will the remaining $5 billion of synergistically induced value be divided?

This is a key issue, requiring intense negotiation between the two management groups. There is no rule or formula to apply, but one basis for the allocation is the relative pre-announcement values of the two companies. For example, in our hypothetical merger of A and B to form AB, the companies might agree to give $\$10/\$25 = 40\%$ of the new stock to A's stockholders and 60% to B's stockholders. Unless a case could be made for giving a higher percentage of the shares to one of the companies because it was responsible for more of the synergistic value, then the pre-merger value proportions would seem to be a "fair" solution. In any event, the pre-merger proportions will probably be given the greatest weight in reaching the final decision.

It should also be noted that control of the consolidated company is always an issue. Generally, the companies hold a press conference and announce that the CEO of one firm will be chairman of the new company, that the other CEO will be president, that the new board will consist of directors from both old boards, and that power will be shared. With huge mergers such as those we have been seeing lately, there is plenty of power to be shared.

SELF-TEST

How does merger analysis differ in the case of a large company acquiring a smaller one versus a "true merger of equals"?

Do you think the same guidelines for allocating synergistic gains would be used in both types of mergers?

22-13 The Role of Investment Bankers

Investment bankers are involved with mergers in five ways: (1) They help arrange mergers. (2) They help target companies develop and implement defensive tactics. (3) They help value target companies. (4) They help finance mergers. (5) They invest in the stocks of potential merger candidates.

22-13a Arranging Mergers

The major investment banking firms have merger and acquisition groups that operate within their corporate finance departments. (Corporate finance departments offer advice, as opposed to underwriting or brokerage services, to business firms.) Members of these groups identify firms with excess cash that might want to buy other firms, companies that might be willing to be bought, and firms that might, for a number of reasons, be attractive to others. Sometimes dissident stockholders of firms with poor track records work with investment bankers to oust management by helping to arrange a merger.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

22-13b Developing Defensive Tactics

Target firms that do not want to be acquired generally enlist the help of an investment banking firm along with a law firm that specializes in mergers. Defenses include such tactics as: (1) changing the bylaws so that only one-third of the directors are elected each year and/or so that a 75% approval (a *super majority*) rather than a simple majority is required to approve a merger, (2) trying to convince the target firm's stockholders that the price being offered is too low, (3) raising antitrust issues in the hope that the Justice Department will intervene, (4) repurchasing stock in the open market in an effort to push the price above that being offered by the potential acquirer, (5) finding a **white knight** who is acceptable to the target firm's management to compete with the potential acquirer and acquire the target (this is called a **defensive merger**), and (6) finding a **white squire** who is friendly to current management and can buy enough of the target firm's shares to block the merger.

22-13c Establishing a Fair Value

If a friendly merger is being worked out between two firms' managements, then it is important to document that the agreed-upon price is a fair one; otherwise, the stockholders of either company may sue to block the merger. Therefore, in most large mergers, each side will hire an investment banking firm to evaluate the target company and to help establish the fair price. Even if the merger is not friendly, investment bankers may still be asked to help establish a price. If a surprise tender offer is to be made, then the acquiring firm will want to know the lowest price at which it might be able to acquire the stock while the target firm may seek help in "proving" that the price being offered is too low.

22-13d Financing Mergers

To be successful in the mergers and acquisitions (M&A) business, an investment banker must be able to offer a financing package to clients—whether they are acquirers who need capital to take over companies or target companies trying to finance stock repurchase plans or other defenses against takeovers. In fact, the fees that investment banks generate through issuing merger-related debt often dwarf their other merger-related fees.

22-13e Arbitrage Operations

Arbitrage generally means simultaneously buying and selling the same commodity or security in two different markets at different prices and pocketing a risk-free return. However, the major brokerage houses, as well as some wealthy private investors, are engaged in a different type of arbitrage called **risk arbitrage**. The *arbitrageurs,* or "arbs," speculate in the stocks of companies that are likely takeover targets. Vast amounts of capital are required to speculate in a large number of securities and thus reduce risk, and also to make money on narrow spreads. Yet the large investment bankers have the wherewithal to play this game. To be successful, arbs must be able to sniff out likely targets, assess the probability of offers reaching fruition, and move in and out of the market quickly and with low transaction costs.

SELF-TEST

What are some defensive tactics that firms can use to resist hostile takeovers?

What is the difference between pure arbitrage and risk arbitrage?

22-14 Who Wins: The Empirical Evidence

The magnitude of the merger market raises two questions: (1) Do corporate acquisitions create value? (2) If so, how is the value shared between the parties?

Most researchers agree that takeovers increase the wealth of the shareholders of target firms; otherwise, they would not agree to the offer. However, there is a debate as to whether mergers benefit the acquiring firm's shareholders. In particular, managements of acquiring firms may be motivated by factors other than maximizing shareholder wealth. For example, they may want to merge merely to increase the size of the corporations they manage, because increased size usually brings larger salaries plus job security, perquisites, power, and prestige.

The question of who gains from corporate acquisitions can be tested by examining the stock price changes that occur around the time of a merger or takeover announcement. Changes in the stock prices of the acquiring and target firms represent market participants' beliefs about the value created by the merger and about how that value will be divided between the target and acquiring firms' shareholders. Therefore, examining a large sample of stock price movements can shed light on the issue of who gains from mergers.

One cannot simply examine stock prices around merger announcement dates, because other factors influence stock prices. For example, if a merger was announced on a day when the entire market advanced, then a rise in the target firm's price would not necessarily signify that the merger was expected to create value. In other words, did the event (in this case, a merger announcement) cause a change in value? Hence, studies examine *abnormal returns* associated with merger announcements, where abnormal returns are defined as that part of a stock price change caused by factors other than changes in the general stock market. Some research defines abnormal returns as the return not explained by an asset pricing model, such as the CAPM or the Fama-French 3-Factor model, as we described in Chapter 6.

Merger Mistakes

Academics have long known that acquiring firms' shareholders rarely reap the benefits of mergers. However, this important information never seemed to make it up to the offices of corporate America's decision makers; the 1990s saw bad deal after bad deal and with no apparent learning on the part of acquisitive executives. *BusinessWeek* published an analysis of 302 large mergers from 1995 to 2001, and it found that 61% of them led to losses by the acquiring firms' shareholders. Indeed, those losing shareholders' returns during the first post-merger year averaged 25 percentage points less than the returns on other companies in their industry. The average returns for all the merging companies, both winners and losers, were 4.3% below industry averages and 9.2% below the S&P 500.

The article cited four common mistakes:

1. The acquiring firms often overpaid. Generally, the acquirers gave away all of the synergies from the mergers to the acquired firms' shareholders, and then some.
2. Management overestimated the synergies (cost savings and revenue gains) that would result from the merger.
3. Management took too long to integrate operations between the merged companies. This irritated customers and employees alike, and it postponed any gains from the integration.
4. Some companies cut costs too deeply at the expense of maintaining sales and production infrastructures.

The worst performance came from companies that paid for their acquisitions with stock. The best performance, albeit a paltry 0.3% better than industry averages, came from companies that used cash for their acquisitions. On the bright side, the shareholders of the companies that were acquired fared quite well, earning on average 19.3% more than their industry peers, and all of those gains came in the two weeks surrounding the merger announcement.

Event studies have examined both acquiring and target firms' stock price responses to mergers and tender offers. Jointly, they have covered nearly every acquisition involving publicly traded firms from the early 1960s to the present, and they are remarkably consistent in their results: On average, the stock prices of target firms increase by about 30% in hostile tender offers, whereas in friendly mergers the average increase is about 20%. However, for both hostile and friendly deals, the stock prices of acquiring firms, on average, remain constant. Thus, the event study evidence strongly indicates that: (1) Acquisitions do create value. (2) Shareholders of target firms reap virtually all the benefits.

The event study evidence suggests that mergers benefit targets but not acquirers—and hence that an acquiring firm's stockholders should be skeptical of its managers' plans for acquisitions. This evidence cannot be dismissed out of hand, but neither is it entirely convincing. There are undoubtedly many good mergers, just as there are many poorly conceived ones. Like most of finance, merger decisions should be studied carefully, and it is best not to judge the outcome of a specific merger until the actual results start to come in.

SELF-TEST

Explain how researchers can study the effects of mergers on shareholder wealth.

Do mergers create value? If so, who profits from this value?

Do the research results discussed in this section seem logical? Explain.

22-15 Corporate Alliances

Mergers are one way for two companies to join forces, but many companies are striking cooperative deals, called **corporate alliances** or **strategic alliances**, which stop far short of merging. Whereas mergers combine all of the assets of the firms involved, as well as their ownership and managerial expertise, alliances allow firms to create combinations that focus on specific business lines that offer the most potential synergies. These alliances take many forms, from simple marketing agreements to joint ownership of worldwide operations.

One form of corporate alliance is the **joint venture**, in which parts of companies are joined to achieve specific, limited objectives. A joint venture is controlled by a management team consisting of representatives of the two (or more) parent companies. A study of 345 corporate alliances found that the stock prices of both partners in an alliance tended to increase when the alliance was announced, with an average abnormal return of about 0.64% on the day of the announcement.[23] About 43% of the alliances were marketing agreements, 14% were R&D agreements, 11% were for licensing technology, 7% for technology transfers, and 25% were for some combination of these four reasons. Although most alliances were for marketing agreements, the market reacted most favorably when the alliance was for technology sharing between two firms in the same industry. The study also found that the typical alliance lasted at least 5 years and that the allied firms had better operating performance than their industry peers during this period.

What is the difference between a merger and a corporate alliance?

What is a joint venture? Give some reasons why joint ventures may be advantageous to the parties involved.

22-16 Divestitures

There are four types of **divestitures**. A *sale to another firm* generally involves the sale of an entire division or unit, usually for cash but sometimes for stock in the acquiring firm. In a **spin-off**, the firm's existing stockholders are given new stock representing separate ownership rights in the division that was divested. The division establishes its own board of directors and officers, and it becomes a separate company. The stockholders end up owning shares of two firms instead of one, but no cash has been transferred. In an **equity carve-out**, a minority interest in a corporate subsidiary is sold to new shareholders, so the parent gains new equity financing yet retains control. In a *liquidation*, the assets of a division are sold off piecemeal to many purchasers rather than as a single operating entity to one purchaser. To illustrate the different types of divestitures, we now present some examples.

In mid-2014, Liberty Media made plans to divest itself of its cable business in an equity carve-out. Shares in the new, publicly traded company, Liberty Broadband, would be distributed to Liberty Media stockholders. This plan followed initial, but later scrapped, plans to create a tracking stock out of this same business line. In 2012, Ralcorp Holdings split the company into a Post Foods piece and a private-label business. The reason for the spin-off was to allow the two divisions to focus on their different product markets and also to allow ConAgra, which had been pursuing Ralcorp for its private-label business, to make a more limited acquisition. In 2009, Time Warner announced that it planned to spin off AOL, the dissolution of a merger that had never worked. And in 2008, Cadbury Schweppes decided to focus on its chocolate and candy businesses, so it spun off soft-drink brands into a separately traded company, the Dr Pepper Snapple Group.

As these examples illustrate, the reasons for divestitures vary widely. Sometimes the market feels more comfortable when firms "stick to their knitting," as the Cadbury Schweppes divestiture illustrates. Sometimes companies need cash either to finance expansion in their primary business lines or to reduce a large debt burden, and divestitures can be used to raise this cash; for example, AMD spun off its manufacturing operations in 2009. The divestitures also show that running a business is a dynamic process—conditions change, corporate strategies change in response, and consequently firms alter their asset portfolios by acquisitions and/or divestitures. Some divestitures are designed to unload losing assets that would otherwise drag the company down, such as Time Warner's spin-off of AOL.

In general, the empirical evidence shows that the market reacts favorably to divestitures, with the divesting company typically having a small increase in stock price on the day of the announcement. The announcement-day returns are largest for companies that "undo" previous conglomerate mergers by divesting businesses in unrelated areas.[24] Studies also show that divestitures generally lead to superior operating performance for both the parent and the divested company.[25]

[24]For details, see Jeffrey W. Allen, Scott L. Lummer, John J. McConnell, and Debra K. Reed, "Can Takeover Losses Explain Spin-off Gains?" *Journal of Financial and Quantitative Analysis*, December 1995, pp. 465–485.

What are some types of divestitures?

What are some motives for divestitures?

22-17 Holding Companies

Holding companies date from 1889, when New Jersey became the first state to pass a law permitting corporations to be formed for the sole purpose of owning the stocks of other companies, which are called **subsidiaries**. Many of the advantages and disadvantages of holding companies are identical to those of any other large-scale organization. Whether a company is organized on a divisional basis or with subsidiaries kept as separate companies does not affect the basic reasons for conducting a large-scale, multiproduct, multiplant operation.

22-17a Advantages and Disadvantages of Holding Companies

There are two principal advantages of a holding company.

1. *Control with fractional ownership.* Through a holding company operation, a firm may buy 5%, 10%, or 50% of the stock of another corporation. Such fractional ownership may be sufficient to give the holding company effective working control over the operations of the company in which it has acquired stock ownership. Working control is often considered to entail more than 25% of the common stock, but it can be as low as 10% if the stock is widely distributed. One financier says that the attitude of management is more important than the number of shares owned: "If management thinks you can control the company, then you do." In addition, control on a very slim margin can be held through relationships with large stockholders outside the holding company group.
2. *Isolation of risks.* Because the various **operating companies** in a holding company system are separate legal entities, the obligations of any one unit are separate from those of the other units. Therefore, catastrophic losses incurred by one unit of the holding company system may not be translatable into claims on the assets of the other units. However, we should note that although this is a customary generalization, it is not always valid. First, the **parent company** may feel obligated to make good on the subsidiary's debts, even though it is not legally bound to do so, in order to keep its good name and to retain customers. Second, a parent company may feel obligated to supply capital to an affiliate in order to protect its initial investment. And third, when lending to one of the units of a holding company system, an astute loan officer may require a guarantee by the parent holding company. To some degree, then, the assets in the various elements of a holding company are not really separate.

The main disadvantage of a holding company involves *partial multiple taxation.* Provided the holding company owns at least 80% of a subsidiary's voting stock, the IRS permits the filing of consolidated returns, in which case dividends received by the parent are not taxed. However, if less than 80% of the stock is owned, then tax returns cannot be consolidated. Firms that own more than 20% but less than 80% of another corporation can deduct 80% of the dividends received, whereas firms that own less than 20% may deduct only 70% of the dividends received. This partial double taxation somewhat offsets the benefits of holding company control with limited ownership, but whether the tax penalty is sufficient to offset other possible advantages varies from case to case.

22-17b Holding Companies as a Leveraging Device

The holding company vehicle has been used to obtain huge degrees of financial leverage. In the 1920s, several tiers of holding companies were established in the electric utility, railroad, and other industries. In those days, an operating company at the bottom of the pyramid might have $100 million of assets, financed by $50 million of debt and $50 million of equity. Then, a first-tier holding company might own the stock of the operating firm as its only asset and be financed with $25 million of debt and $25 million of equity. A second-tier holding company, which owned the stock of the first-tier company, might be financed with $12.5 million of debt and $12.5 million of equity. Such systems were extended to five or six levels. With six holding companies, $100 million of operating assets could be controlled at the top by only $0.78 million of equity, and the operating assets would have to provide enough cash income to support $99.22 million of debt. *Such a holding company system is highly leveraged—its consolidated debt ratio is 99.22%, even though each of the individual components shows only a 50% debt/assets ratio.* Because of this consolidated leverage, even a small decline in profits at the operating company level could bring the whole system down like a house of cards. This situation existed in the electric utility industry in the 1920s, and the Depression of the 1930s wreaked such havoc with the holding companies that federal legislation was enacted that constrained holding companies in that industry.

SELF-TEST

What is a holding company?

What are some of the advantages of holding companies? Identify a disadvantage.

SUMMARY

- A **merger** occurs when two firms combine to form a single company. The primary motives for mergers are: (1) synergy, (2) tax considerations, (3) purchase of assets below their replacement costs, (4) diversification, (5) gaining control over a larger enterprise, and (6) breakup value.
- Mergers can provide economic benefits through **economies of scale** and through putting assets in the hands of more efficient managers. However, mergers also have the potential for reducing competition, and for this reason they are carefully regulated by government agencies.
- In most mergers, one company (the **acquiring company**) initiates action to take over another (the **target company**).
- A **horizontal merger** occurs when two firms in the same line of business combine.
- A **vertical merger** combines a firm with one of its customers or suppliers.
- A **congeneric merger** involves firms in related industries but where no customer–supplier relationship exists.
- A **conglomerate merger** occurs when firms in totally different industries combine.
- In a **friendly merger**, the managements of both firms approve the merger, whereas in a **hostile merger**, the target firm's management opposes it.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- An **operating merger** is one in which the operations of the two firms are combined. A **financial merger** is one in which the firms continue to operate separately; hence, no operating economies are expected.
- In a typical merger analysis, the key issues to be resolved are: (1) the price to be paid for the target firm and (2) the employment/control situation. If the merger is a consolidation of two relatively equal firms, at issue is the percentage of ownership that each merger partner's shareholders will receive.
- Four methods are commonly used to determine the value of the target firm: (1) market multiple analysis, (2) the free cash flow corporate valuation model, (3) the free cash flow to equity (FCFE) model, and (4) the compressed adjusted present value (CAPV) model. Of the discounted cash flow approaches, only the compressed APV model is appropriate if the capital structure is changing during the forecast period.
- **Purchase accounting** treats mergers as a purchase and is used for financial reporting.
- A **joint venture** is a **corporate alliance** in which two or more companies combine some of their resources to achieve a specific, limited objective.
- A **divestiture** is the sale of some of a company's operating assets. A divestiture may involve: (1) selling an operating unit to another firm, (2) **spinning off** a unit as a separate company, (3) **carving out** a unit by selling a minority interest, or (4) the outright liquidation of a unit's assets.
- The reasons for divestiture include: (1) settling antitrust suits, (2) improving the transparency of the resulting companies so that investors can more easily evaluate them, (3) enabling management to concentrate on a particular type of activity, and (4) raising the capital needed to strengthen the corporation's core business.
- A **holding company** is a corporation that owns sufficient stock in another firm to control it. The holding company is also known as the **parent company**, and the companies that it controls are called **subsidiaries** or **operating companies**.
- Holding company operations are advantageous because: (1) Control can often be obtained for a smaller cash outlay. (2) Risks may be segregated. (3) Regulated companies can operate separate subsidiaries for their regulated and unregulated businesses.
- A major disadvantage to holding companies is the possibility of income being taxed at the subsidiary and at the parent.

QUESTIONS

(22-1) Define each of the following terms:

a. Synergy; merger
b. Horizontal merger; vertical merger; congeneric merger; conglomerate merger
c. Friendly merger; hostile merger; defensive merger; tender offer; target company; breakup value; acquiring company
d. Operating merger; financial merger
e. Free cash flow to equity
f. Purchase accounting
g. White knight; proxy fight
h. Joint venture; corporate alliance

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

i. Divestiture; spin-off
j. Holding company; operating company; parent company
k. Arbitrage; risk arbitrage

(22-2) Four economic classifications of mergers are: (1) horizontal, (2) vertical, (3) conglomerate, and (4) congeneric. Explain the significance of these terms in merger analysis with regard to (a) the likelihood of governmental intervention and (b) possibilities for operating synergy.

(22-3) Firm A wants to acquire Firm B. Firm B's management agrees that the merger is a good idea. Might a tender offer be used? Why or why not?

(22-4) Distinguish between operating mergers and financial mergers.

(22-5) Explain why the APV model is suited for situations in which the capital structure is changing during the forecast period.

SELF-TEST PROBLEM

Solution Shown in Appendix A

(ST-1) Valuation of Target

Red Valley Breweries is considering an acquisition of Flagg Markets. Flagg currently has a cost of equity of 10%; 25% of its financing is in the form of 6% debt, and the rest is in common equity. Its federal-plus-state tax rate is 40%. After the acquisition, Red Valley expects Flagg to have the FCFs and interest payments for the next 3 years (in millions) shown in the following table. After the explicit forecast period, the free cash flows are expected to grow at a constant rate of 5%, and the capital structure will stabilize at 35% debt with an interest rate of 7%. Use the compressed adjusted present value approach to answer the following questions.

	Year 1	Year 2	Year 3
FCF	$10.00	$20.00	$25.00
Interest expense	28.00	24.00	20.28

a. What is Flagg's unlevered cost of equity? What are its levered cost of equity and cost of capital for the post-horizon period?
b. What is Flagg's value of operations to Red Valley?

PROBLEMS

Answers Are in Appendix B

EASY PROBLEM 1

(22-1) Valuation of Merger Target

Hastings Corporation is interested in acquiring Vandell Corporation. Vandell has 1 million shares outstanding and a target capital structure consisting of 30% debt; its beta is 1.4 (given its target capital structure). Vandell has $10.82 million in debt that trades at par and pays an 8% interest rate. Vandell's free cash flow (FCF_0) is $2 million per year and is expected to grow at a constant rate of 5% a year. Vandell pays a 40% combined federal and state tax rate. The risk-free rate of interest is 5% and the market risk premium is 6%. Hastings's first step is to estimate the current intrinsic value of Vandell.

a. What are Vandell's cost of equity and weighted average cost of capital?
b. What is Vandell's intrinsic value of operations? (*Hint:* Use the free cash flow corporate valuation model from Chapter 7.)
c. What is the current intrinsic value of Vandell's stock?

INTERMEDIATE PROBLEMS 2–3

(22-2) Merger Valuation with the CAPV Model

Hastings Corporation estimates that if it acquires Vandell Corporation, synergies will cause Vandell's free cash flows to be $2.5 million, $2.9 million, $3.4 million, and $3.57 million at Years 1 through 4, respectively, after which the free cash flows will grow at a constant 5% rate. Hastings plans to assume Vandell's $10.82 million in debt (which has an 8% interest rate) and raise additional debt financing at the time of the acquisition. Hastings estimates that interest payments will be $1.5 million each year for Years 1, 2, and 3. After Year 3, a target capital structure of 30% debt will be maintained. Interest at Year 4 will be $1.472 million, after which the interest and the tax shield will grow at 5%. As described in Problem 22-1, Vandell currently has 1 million shares outstanding and a target capital structure consisting of 30% debt; its current beta is 1.4 (i.e., based on its target capital structure).

a. What is Vandell's pre-acquisition levered cost of equity? What is its unlevered cost of equity? (*Hint:* You can use the pre-acquisition levered cost of equity you determined previously if you worked Problem 22-1.)
b. What is the intrinsic unlevered value of operations at $t = 0$ (assuming the synergies are realized)?
c. What is the value of the tax shields at $t = 0$?
d. What is the total intrinsic value of operations at $t = 0$? What is the intrinsic value of Vandell's equity to Hastings? What is Vandell's intrinsic stock price per share?

(22-3) Merger Bid

On the basis of your answers to Problems 22-1 and 22-2, indicate the range of possible prices that Hastings could bid for each share of Vandell common stock in an acquisition.

CHALLENGING PROBLEMS 4–6

(22-4) Merger Valuation with Change in Capital Structure

Hastings Corporation estimates that if it acquires Vandell Corporation, synergies will cause Vandell's free cash flows to be $2.5 million, $2.9 million, $3.4 million, and $3.57 million at Years 1 through 4, respectively, after which the free cash flows will grow at a constant 5% rate. Hastings plans to assume Vandell's $10.82 million in debt and raise additional debt financing at the time of the acquisition. Hastings estimates that interest payments will be $1.5 million each year for Years 1, 2, and 3. Unlike Problem 22-3, suppose Hastings will increase Vandell's level of debt at Year 3 to $30.6 million so that the target capital structure becomes 45% debt. Assume that with this higher level of debt, the interest rate would be 8.5%, and assume that interest payments in Year 4 are based on the new debt level at Year 3 and the 8.5% interest rate. The Year-4 interest expense is expected to grow at 5% after Year 4. As described in Problem 22-1, Vandell currently has 1 million shares outstanding and a target capital structure consisting of 30% debt; its current beta is 1.4 (i.e., based on its target capital structure).

a. What is the Year-4 interest expense? What is the Year-4 tax shield?
b. What is the unlevered value of operations? What is the value of the tax shield? (*Hint:* You can use the pre-acquisition unlevered cost of equity you determined previously if you worked Problem 22-2; you can also use the unlevered value of operations you determined previously if you worked Problem 22-2.)
c. What is the maximum price per share that Hastings would bid for Vandell? How does it compare with your answers to Problems 22-1 and 22-2?

(22-5) Merger Analysis

Marston Marble Corporation is considering a merger with the Conroy Concrete Company. Conroy is a publicly traded company, and its beta is 1.30. Conroy has been barely profitable, so it has paid an average of only 20% in taxes during the last several years. In addition, it uses little debt; its target ratio is just 25%, with the cost of debt 9%.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

If the acquisition were made, Marston would operate Conroy as a separate, wholly owned subsidiary. Marston would pay taxes on a consolidated basis, and the tax rate would therefore increase to 35%. Marston also would increase the debt capitalization in the Conroy subsidiary to $w_d = 40\%$, for a total of $22.27 million in debt by the end of Year 4, and pay 9.5% on the debt. Marston's acquisition department estimates that Conroy, if acquired, would generate the following free cash flows and interest expenses (in millions of dollars) in Years 1–5:

Year	Free Cash Flows	Interest Expense
1	$1.30	$1.2
2	1.50	1.7
3	1.75	2.8
4	2.00	2.1
5	2.12	?

In Year 5, Conroy's interest expense would be based on its beginning-of-year (that is, the end-of-Year-4) debt, and in subsequent years both interest expense and free cash flows are projected to grow at a rate of 6%.

These cash flows include all acquisition effects. Marston's cost of equity is 10.5%, its beta is 1.0, and its cost of debt is 9.5%. The risk-free rate is 6%, and the market risk premium is 4.5%. Use the compressed APV model to answer the following questions.

a. What is the value of Conroy's unlevered operations, and what is the value of Conroy's tax shields under the proposed merger and financing arrangements?
b. What is the dollar value of Conroy's operations? If Conroy has $10 million in debt outstanding, how much would Marston be willing to pay for Conroy?

(22-6) Merger Valuation with Change in Capital Structure

VolWorld Communications Inc., a large telecommunications company, is evaluating the possible acquisition of Bulldog Cable Company (BCC), a regional cable company. VolWorld's analysts project the following post-merger data for BCC (in thousands of dollars, with a year-end of December 31):

	2016	2017	2018	2019	2020	2021
Net sales		$450	$518	$ 555	$ 600	$ 643
Selling and administrative expense		45	53	60	68	73
Interest		40	45	47	52	54
Total net operating capital	$800	850	930	1,005	1,075	1,150

Tax rate after merger: 35%
Cost of goods sold as a percent of sales: 65%
BCC's pre-merger beta: 1.40
Risk-free rate: 6%
Market risk premium: 4%
Terminal growth rate of free cash flows: 7%

If the acquisition is made, it will occur on January 1, 2017. All cash flows shown in the income statements are assumed to occur at the end of the year. BCC currently has a capital structure of 40% debt, which costs 10%, but over the next 4 years VolWorld would increase that to 50%, and the target capital structure would be reached by the start of 2021. BCC, if independent, would pay taxes at 20%, but its income would be taxed at 35%

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

if it were consolidated. BCC's current market-determined beta is 1.4. The cost of goods sold is expected to be 65% of sales. Use the compressed APV approach to answer the following questions.

a. What is the unlevered cost of equity for BCC?
b. What are the free cash flows and interest tax shields for the first 5 years?
c. What is BCC's horizon value of interest tax shields and unlevered horizon value?
d. What is the value of BCC's equity to VolWorld's shareholders if BCC has $300,000 in debt outstanding now?

SPREADSHEET PROBLEM

(22-7) Build a Model: Merger Analysis

resource

Start with the partial model in the file ***Ch22 P07 Build a Model.xlsx*** on the textbook's Web site. Wansley Portal Inc., a large Internet service provider, is evaluating the possible acquisition of Alabama Connections Company (ACC), a regional Internet service provider. Wansley's analysts project the following post-merger data for ACC (in thousands of dollars):

	2017	2018	2019	2020	2021
Net sales	$500	$600	$700	$760	$806
Selling and administrative expense	60	70	80	90	96
Interest	30	40	45	60	74

If the acquisition is made, it will occur on January 1, 2017. All cash flows shown in the income statements are assumed to occur at the end of the year. ACC currently has a capital structure of 30% debt, which costs 9%, but Wansley would increase that over time to 40%, costing 10%, if the acquisition were made. ACC, if independent, would pay taxes at 30%, but its income would be taxed at 35% if it were consolidated. ACC's current market-determined beta is 1.4. The cost of goods sold, which includes depreciation, is expected to be 65% of sales, but it could vary somewhat. Required gross investment in operating capital is approximately equal to the depreciation charged, so there will be no investment in net operating capital. The risk-free rate is 7%, and the market risk premium is 6.5%. Wansley currently has $400,000 in debt outstanding. Use the compressed APV model to answer the following questions.

a. What is the unlevered cost of equity?
b. What are the horizon value of the tax shields and the horizon value of the unlevered operations? What are the value of ACC's operations and the value of ACC's equity to Wansley's shareholders?

MINI CASE

Hager's Home Repair Company, a regional hardware chain that specializes in "do it yourself" materials and equipment rentals, is cash rich because of several consecutive good years. One of the alternative uses for the excess funds is an acquisition. Doug Zona, Hager's treasurer and your boss, has been asked to place a value on a potential target, Lyons Lighting (LL), a chain that operates in several adjacent states, and he has enlisted your help.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The following table indicates Zona's estimates of LL's earnings potential if it came under Hager's management (in millions of dollars). The interest expense listed here includes the interest: (1) on LL's existing debt, which is $55 million at a rate of 9%, and (2) on new debt expected to be issued over time to help finance expansion within the new "L division," the code name given to the target firm. If acquired, LL will face a 40% tax rate.

Security analysts estimate LL's beta to be 1.3. The acquisition would not change Lyons's capital structure, which is 20% debt. Zona realizes that Lyons Lighting's business plan also requires certain levels of operating capital and that the annual investment could be significant. The required levels of total net operating capital are listed in the table.

Zona estimates the risk-free rate to be 7% and the market risk premium to be 4%. He also estimates that free cash flows after 2020 will grow at a constant rate of 6%. Following are projections for sales and other items.

	2016	2017	2018	2019	2020	2021
Net sales		$ 60.00	$ 90.00	$112.50	$127.50	$139.70
Cost of goods sold (60%)		36.00	54.00	67.50	76.50	83.80
Selling/administrative expense		4.50	6.00	7.50	9.00	11.00
Interest expense		5.00	6.50	6.50	7.00	8.16
Total net operating capital	$150.00	150.00	157.50	163.50	168.00	173.00

Hager's management is new to the merger game, so Zona has been asked to answer some basic questions about mergers as well as to perform the merger analysis. To structure the task, Zona has developed the following questions, which you must answer and then defend to Hager's board.

a. Several reasons have been proposed to justify mergers. Among the more prominent are: (1) tax considerations, (2) risk reduction, (3) control, (4) purchase of assets at below replacement cost, (5) synergy, and (6) globalization. In general, which of the reasons are economically justifiable? Which are not? Which fit the situation at hand? Explain.
b. Briefly describe the differences between a hostile merger and a friendly merger.
c. What are the steps in valuing a merger using the compressed APV approach?
d. Use the data developed in the table to construct the L division's free cash flows for 2017 through 2021. Why are we identifying interest expense separately when it is not normally included in calculating free cash flows or in a capital budgeting cash flow analysis? Why is investment in net operating capital included when calculating the free cash flow?
e. Conceptually, what is the appropriate discount rate to apply to the cash flows developed in Part c? What is your actual estimate of this discount rate?
f. What is the estimated horizon, or continuing, value of the acquisition; that is, what is the estimated value of the L division's cash flows beyond 2021? What is LL's value to Hager's shareholders? Suppose another firm were evaluating LL as an acquisition candidate. Would it obtain the same value? Explain.
g. Assume that LL has 20 million shares outstanding. These shares are traded relatively infrequently, but the last trade (made several weeks ago) was at a price of $11 per share. Should Hager's make an offer for Lyons Lighting? If so, how much should it offer per share?
h. How would the analysis be different if Hager's intended to recapitalize LL with 40% debt costing 10% at the end of 4 years? This amounts to $221.6 million in debt as of the end of 2020.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

i. There has been considerable research undertaken to determine whether mergers really create value and, if so, how this value is shared between the parties involved. What are the results of this research?
j. What method is used to account for mergers?
k. What merger-related activities are undertaken by investment bankers?
l. What are the major types of divestitures? What motivates firms to divest assets?
m. What are holding companies? What are their advantages and disadvantages?

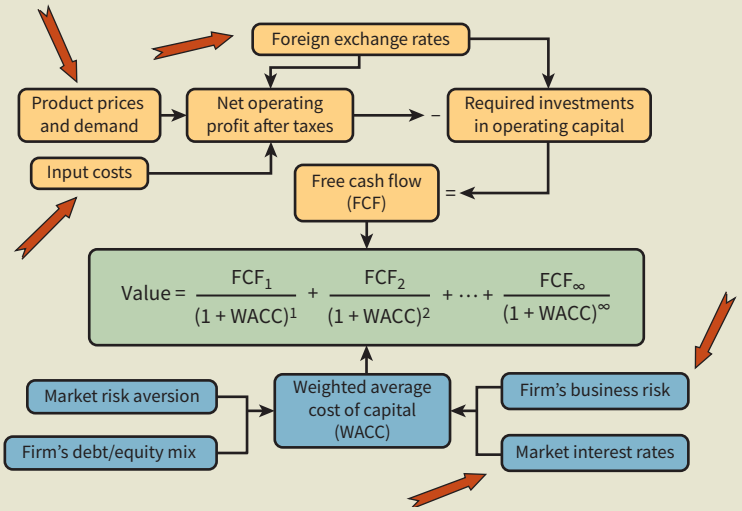
CHAPTER 23

Enterprise Risk Management

On April 13, 2012, JPMorgan Chase CEO Jamie Dimon called rumors of impending trading losses a "tempest in a teapot." As time passed, the losses exceeded $6 billion and led to several criminal charges for hiding losses, making it a pretty big teapot!

Banks make loans to businesses, and JPMorgan is no exception. Many of its borrowers were exposed to difficult global economic conditions, including the Eurozone crises, which in turn exposed JPMorgan to risk. To offset potential losses on commercial lending, JPMorgan's Chief Investment Office in London took short positions on selected indexes that would pay off if some large companies, including some of their customers, defaulted on bank loans.[1] This is a classic hedge—if borrowers defaulted, JPMorgan's commercial lending group would lose money, but the London office would make money, and vice versa.

However, that is not the end of the story. The London office also took long positions on derivatives based on a broader credit index, the CDX.NA.IG.9. (Long positions meant that JPMorgan made commitments to buy at a fixed price.) Their intentions were to reduce expenses but also to hedge their short positions in the selected indexes, betting that the selected indexes were temporarily mispriced relative to the IG.9. JPMorgan continued to take long positions on the IG.9 during late 2011 and early 2012, until it became the biggest trader in this segment of the market. In fact, it is likely that JPMorgan's own trading activities artificially drove down the IG.9's price.



The low price of the IG.9 attracted hedge funds, and what goes down must come up. As the IG.9 price increased, JPMorgan began to lose money on its long positions and started liquidating some if its positions to prevent even bigger losses in the future. Keep this episode in mind as you read the rest of the chapter.

[1]These indexes were actually composed of credit default swaps, so JPMorgan was going short in a derivative based on other derivatives.

Corporate Valuation and Risk Management

All companies are exposed to risk from volatility in product prices, demand, input costs, and other sources of business risk, such as the risk stemming from the choice of production technology. Many companies also are exposed to risk from volatility in exchange rates and interest rates. Risk management can reduce firm risk, preventing catastrophes and leading to a lower cost of capital. In some instances, derivatives such as swaps can reduce the effective interest rate paid by a corporation, again reducing its cost of capital.

resource

The textbook's Web site contains an Excel *file that will guide you through the chapter's calculations. The file for this chapter is* ***Ch23 Tool Kit.xlsx****, and we encourage you to open the file and follow along as you read the chapter.*

Defining risk management is simple: Identify events that could have adverse consequences and then take actions to prevent or minimize the damage caused by these events. Applying risk management is more difficult, but it is vital for a company's success, and perhaps even its survival. In this chapter we explain how risk management adds value to a corporation, describe an enterprise risk management framework, identify different categories of risks, explain how to measure selected risks, and show how to manage those risks.[2] We also illustrate how companies can use **derivatives**, which are securities whose values are determined by the market price of some other asset, to manage certain types of risk.

23-1 Reasons to Manage Risk

Hedging is a risk management technique in which a company can reduce or eliminate its exposure to a source of risk through the use of derivatives. But will reducing risk make a company more valuable? Consider Plastic Inc., which manufactures dashboards, interior door panels, and other plastic components used by auto companies. Petroleum is the key feedstock for plastic and thus makes up a large percentage of its costs. Plastic has a 3-year

[2]For excellent overviews of risk management, see Kenneth A. Froot, David S. Scharfstein, and Jeremy Stein, "A Framework for Risk Management," *Journal of Applied Corporate Finance*, Fall 1994, pp. 22–32; Brian Nocco and Rene Stultz, "Enterprise Risk Management, Theory and Practice," *Journal of Applied Corporate Finance*, Fall 2006, pp. 8–20; Walter Dolde, "The Trajectory of Corporate Financial Risk Management," *Journal of Applied Corporate Finance*, Fall 1993, pp. 33–41; and Marshall Blake and Nelda Mahady, "How Mid-Sized Companies Manage Risk," *Journal of Applied Corporate Finance*, Spring 1991, pp. 59–65.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. contract with an auto company to deliver 500,000 door panels each year at a price of $20 each. When the company recently signed this contract, oil sold for $100 per barrel and was expected to stay at that level for the next 3 years. If oil prices fell during this time, Plastic would have higher than expected profits and free cash flows, but if oil prices rose, profits would fall. Because Plastic's value depends on its profits and free cash flows, a change in the price of oil would cause stockholders to earn either more or less than they anticipated.

Now suppose that, shortly after signing the contract with its door panel supplier, Plastic announces that it plans to lock in a 3-year supply of oil at a guaranteed price of $100 per barrel *and* that the cost of this guarantee is zero. Would that cause its stock price to rise? At first glance, it seems the answer should be "yes," but that might not be correct. Recall that the value of a stock depends on the present value of its expected future free cash flows, discounted at the weighted average cost of capital (WACC). Locking in the cost of oil will cause an increase in Plastic's stock price if and only if it produces at least one of these two results: (1) Expected future free cash flows increase. (2) The WACC declines.

Consider first the free cash flows. Before the announcement of guaranteed oil costs, investors had formed an estimate of the expected future free cash flows based on an expected oil price of $100 per barrel. Locking in the cost of oil at $100 per barrel will lower the *risk* of the expected future free cash flows, but it might not change the expected *size* of these cash flows because investors already expected a price of $100 per barrel. Of course, smaller than expected cash flows can disrupt a firm's operation and that disruption can, in turn, adversely affect cash flows.

Now what about the WACC? It will change only if locking in the cost of oil causes a change either in the cost of debt or equity or in the target capital structure. If the foreseeable increases in the price of oil are not enough to increase the threat of bankruptcy, then Plastic's cost of debt should not change and neither should its target capital structure. Regarding the cost of equity, recall from Chapter 6 that most investors hold well-diversified portfolios, which means that the cost of equity should depend only on systematic risk. Moreover, even though an increase in oil prices would have a negative effect on Plastic's stock price, it would not have a negative effect on all stocks. Indeed, oil producers should have higher than expected returns and stock prices. Assuming that Plastic's investors hold well-diversified portfolios that include stocks of oil-producing companies, we should have little reason to expect its cost of equity to decrease. The bottom line is this: If Plastic's expected future cash flows and WACC will not change significantly as a consequence of eliminating the risk of oil price increases, then neither should the value of its stock.

We discuss futures contracts and hedging in detail in the next section, but for now let's assume that Plastic has *not* locked in oil prices. Therefore, if oil prices increase, its stock price will fall. However, if its stockholders know this, they can build portfolios that contain oil futures whose values will rise or fall with oil prices and thus offset changes in the price of Plastic's stock. By choosing the correct amount of futures contracts, investors can thus "hedge" their portfolios and completely eliminate the risk due to changes in oil prices. There will be a cost to hedging, but that cost to large investors should be about the same as the cost to Plastic. Because stockholders can hedge away oil price risk themselves, why should they pay a higher price for Plastic's stock just because the company itself hedged away that risk?

The previous points notwithstanding, companies clearly believe that active risk management is important. A 1998 survey reported that 83% of firms with market values greater than $1.2 billion engage in risk management.[3] A more recent 2005 survey of CFOs

[3]See Gordon M. Bodnar, Gregory S. Hayt, and Richard C. Marston, "1998 Wharton Survey of Financial Risk Management by U.S. Non-Financial Firms," *Financial Management*, Winter 1998, pp. 70–91.

reported that 90% of the international and domestic firms responding considered risk in the planning process. The average of the estimates of the contribution that risk management made to the market value of the firm was 3.8%.[4] There are many reasons why companies manage their risks.

1. *Debt capacity*. Risk management can reduce the volatility of cash flows, which decreases the probability of bankruptcy. As we discussed in Chapter 15, firms with lower operating risks can use more debt, and this can lead to higher stock prices due to the interest tax savings.
2. *Maintaining the optimal capital budget over time*. Recall from Chapter 15 that firms are reluctant to raise external equity because of high flotation costs and market pressure. This means that the capital budget must generally be financed with a combination of debt and internally generated funds. In bad years, internal cash flows may be too low to support the optimal capital budget, causing firms to either slow investment below the optimal rate or else incur the high costs associated with external equity. By smoothing out the cash flows, risk management can alleviate this problem. This issue is most relevant for firms with large growth opportunities. A study by Professors Gerald Gay and Jouahn Nam found that such firms do in fact use derivatives more than low-growth firms.[5] Thus, maintaining an optimal capital budget is an important determinant of firms' risk management practices.
3. *Financial distress*. The stages of financial distress can range from stockholder concern and higher interest rates on debt to customer defections and bankruptcy. Any serious level of financial distress causes a firm to have lower cash flows than expected. Risk management can reduce the likelihood of low cash flows and hence of financial distress.
4. *Comparative advantages in hedging*. Most investors cannot hedge as efficiently as a company. First, firms generally incur lower transaction costs because of their larger volume of hedging activities. Second, there is the problem of asymmetric information: Managers know more about the firm's risk exposure than do outside investors, so managers can create more effective hedges. And third, effective risk management requires specialized skills and knowledge that firms are more likely to have.
5. *Borrowing costs*. As discussed later in the chapter, firms can sometimes reduce input costs—especially the interest rate on debt—through the use of derivative instruments called *swaps*. Any such cost reduction adds value to the firm.
6. *Tax effects*. The present value of taxes paid by companies with volatile earnings is higher than the present value of taxes paid by stable companies; this is because of the treatment of tax credits and the rules governing corporate loss carryforwards and carrybacks. Moreover, if volatile earnings cause a company to declare bankruptcy, then the company often will lose the value of its tax loss carryforwards. Therefore, using risk management to stabilize earnings can reduce the present value of a company's tax burden.
7. *Compensation systems*. Many compensation systems establish "floors" and "ceilings" on bonuses and also reward managers for meeting targets. To illustrate, suppose a firm's compensation system calls for a manager to receive no bonus if net income is below $1 million, a bonus of $10,000 if income is between $1 million and $2 million, or a bonus of $20,000 if income is $2 million or more. The manager will also receive

an additional $10,000 if actual income is at least 90% of the forecasted level, which is $1 million. Now consider the following two situations. First, if income is stable at $2 million each year then the manager receives a $30,000 bonus each year, for a 2-year total of $60,000. However, if income is zero the first year and $4 million the second, the manager gets no bonus the first year and gets $30,000 the second, for a 2-year total of $30,000. So, even though the company has the same total income ($4 million) over the 2 years, the manager's bonus is higher if earnings are stable. Therefore, even if hedging does not add much value for stockholders, it may still benefit managers.

There are regulatory and economically driven reasons to manage risk. The following section describes a typical enterprise risk management framework.

SELF-TEST

Explain why finance theory, combined with well-diversified investors and "homemade hedging," might suggest that risk management should not add much value to a company.

List and explain some reasons companies might employ risk management techniques.

23-2 An Overview of Enterprise Risk Management

The practice of enterprise risk management has evolved considerably over the last 20 years, due to advances in technology and regulatory changes. To better explain the framework for enterprise risk management, we begin with a brief history of risk management.

One of the earliest used tools in risk management is a futures contract, which is an agreement in which a buyer pledges to purchase a specific quantity of an item at a specific price on a specific future date from a seller who has pledged to provide the item at the agreed-upon terms. Written records show that commodity futures contracts were used and traded more than 4,000 years ago in India, so risk management has been around a very long time. In the United States, grain traders used futures contracts as far back as the early 1800s.[6]

The history of insurance also dates back hundreds of years, with maritime insurance offered in Genoa in the 1300s and fire insurance offered in London in 1680, not long after the Great Fire of London. In fact, Benjamin Franklin and the Union Fire Company began a fire insurance company in 1752.

As the previous examples illustrate, commodity futures contracts and insurance have been used worldwide for centuries. At the risk of oversimplification, not much new happened until the 1970s, probably because several sources of risk (interest rates, currency exchange rates, and oil prices) had been relatively stable, and perhaps because models for options and other derivatives had not yet been developed. However, the 1970s saw the end of the monetary gold standard (which dramatically increased foreign exchange rate volatility), runaway inflation in the United States, and a reversal in bargaining power between OPEC and oil companies during the Yom Kippur War between Egypt and Israel in 1973. These events, combined with the acceleration of international competition, exposed companies to much more risk than in the previous decades. In turn, these sources of risk made stocks, bonds, and other investments much more volatile.

With the development of pricing models for derivatives, most companies began to actively manage their exposures to interest rates, exchange rates, and a wide variety of commodities. However, few companies employed a systematic approach to risk

[6]For a thorough treatment of the history of enterprise risk management, see Betty Simkins and Steven A. Ramirez, "Enterprise-Wide Risk Management and Corporate Governance," *Loyola University Chicago Law Journal*, Vol. 39, 2008, pp. 571–594.

management. Instead, most companies had a risk management group in charge of insurance-related issues, but different groups in charge of managing each of the other specific risks. For example, one group might manage foreign exchange risk and another might manage commodity risk.

The impetus for a more comprehensive and systematic approach to risk management came from several sources, including corporate bribery scandals in the 1970s, the S&L crisis in the early 1980s, the accounting scandals in the early 2000s (including Enron and WorldCom), and the banking crisis in the late 2000s. All of these events had several common factors, including accounting systems that lacked sufficient controls to identify improper activities.

Regulators responded to each of these crises in an effort to assign blame and prevent the next crisis. In 1977, Congress passed the Foreign Corrupt Practices Act (FCPA) to prevent corporate bribery, and one of its provisions requires companies to have an accounting system that can identify funds used for bribery. In the mid-1980s, a congressional committee examined the S&L failures and found that some of the failed financial institutions had fraudulent financial statements. In addition to criticizing accounting standards, this committee hinted that Congress and the SEC would impose additional regulatory controls if the accounting profession did not take actions to prevent similar frauds. In 2002, Congress passed the Sarbanes-Oxley (SOX) Act to prevent accounting scandals like those that occurred at Enron, Arthur Andersen, and Tyco. Section 404 of SOX requires senior management to include a section in the annual report that addresses the internal control system, including the system's framework and an assessment of its ability to detect fraud.

In response to stinging criticism from Congress, five major accounting organizations formed the Committee of Sponsoring Organizations (COSO) and released several reports, including one in 1992 that provided a framework for an internal control system designed to prevent fraudulent accounting. The framework for the COSO accounting internal control system satisfied the reporting requirements made by the Foreign Corrupt Practices Act (FCPA) and SOX, so many companies adopted the framework. In 2004, COSO also issued a framework for enterprise risk management, which broadened the scope of the original internal control framework. Because many companies were already using the framework for internal controls, some adopted versions of the broader framework for enterprise risk management. Today, the COSO framework and similar frameworks are widely used.

COSO defines **enterprise risk management (ERM)** as follows:

> Enterprise risk management is a *process,* effected by an entity's *board of directors*, management and other personnel, applied in *strategy setting* and across the *enterprise,* designed to identify *potential events* that may affect the entity, and manage risk to be within its *risk appetite*, to provide reasonable *assurance* regarding the achievement of entity objectives.[7]

Notice how this definition differs from the traditional compartmentalization of risk management. The COSO framework is inclusive, starting with the board of directors in addition to managers and other employees; COSO is broad in defining risk, ranging from strategic choices to specific events; COSO is unambiguous, with the company explicitly choosing an acceptable level of risk; and COSO is transparent, requiring monitoring and reporting.

Before we describe ERM frameworks in more detail, you should know about the Basel accords, another big regulatory wave that has had an impact on risk management. The Basel

Committee, headquartered in Switzerland, is composed of the heads of the central banks from well-developed economies. In the past 25 years, the Committee has introduced three major accords designed to control risk in the global financial system, Basel I (1988), Basel II (2004), and Basel III (introduced in 2010 and revised in 2011). There are similarities in all three accords, but we focus on Basel III because it is the most recent.

The essence of banking is raising funds (from sales of stock, issuances of debt, borrowing through short-term loans, and taking deposits) and then investing the funds in assets (such as business loans and derivatives). A bank experiences financial distress when its assets' cash flows and values aren't sufficient to cover its obligations to its creditors. To prevent a bank from experiencing financial distress (and then passing its problems on to taxpayers and the global financial system), Basel III seeks to ensure that a bank is not financed with too much debt relative to the risk of its assets. In addition to regulations regarding the types and proportions of capital a bank must maintain relative to its assets' risks, Basel III also requires adequate internal control systems to supervise a bank's risk and goes on to suggest particular techniques for measuring risk. We will describe several of these measures later in the chapter, including *value at risk* and *expected shortfall.*

SELF-TEST

Describe some regulatory actions that have influenced the evolution of risk management.

Define enterprise risk management.

23-3 A Framework for Enterprise Risk Management

No single framework is applicable to all companies, but the COSO framework (including modified versions) is widely used, so it provides an excellent example of an ERM framework.[8]

23-3a The Committee of Sponsoring Organizations' (COSO) Framework for Enterprise Risk Management (ERM)

COSO designed its enterprise risk management framework with three dimensions. The first dimension is the organizational level. The COSO framework applies ERM at all levels of an organization, including the corporate level, division levels, business units, and subsidiaries.

The second dimension is the category of objectives. Each organizational level should define its objectives in each of four categories: (1) *strategic objectives,* which are based on the company's mission and overall goals; (2) *operating objectives,* which focus on the selection, implementation, and ongoing execution of projects and other applications of corporate resources; (3) *reporting objectives,* which seek to disseminate accurate and up-to-date information to decision makers inside the company and stakeholders outside the company (such as investors and regulators); and (4) *compliance objectives,* which seek to ensure the company complies with laws and regulatory requirements.

[8]For more on the COSO framework, see The Committee of Sponsoring Organizations of the Treadway Commission, *Enterprise Risk Management—Integrated Framework,* 2004, available at **www.coso.org/guidance.htm**. A summary of the framework is available for free at the same Web site. Another widely used framework is ISO 3100:2009, published by the International Organization for Standardization (ISO), headquartered in Switzerland. For an ERM framework that is consistent with COSO and ISO, see **https://www.theirm.org/knowledge-and-resources/online-resource-centre/enterprise-risk-management/erm-general/a-structured-approach-to-enterprise-risk-management-(erm)-and-the-requirements-of-iso-31000,-irm,-2010/** a report that is authored jointly by three major UK risk management associations.

The third dimension is the process of risk management for an objective at a particular level within the organization. The risk management process for each objective has eight components, which we discuss in the following section.

23-3b The Components of the COSO Enterprise Risk Management Framework

The eight components of the COSO ERM process define the way in which an organization approaches and applies risk management.

COMPONENTS 1 AND 2: INTERNAL ENVIRONMENT AND OBJECTIVE SETTING

The first two components are related to a company's culture and mission, including the company's workplace environment, attitude toward risk, and goal-setting process. An important part of these processes is the identification of the amount of risk that a company is willing to take, which often is called the *risk appetite*.

COMPONENT 3: EVENT IDENTIFICATION

You can't manage a source of risk if you don't recognize it. A **risky event** is defined as any uncertain outcome that affects a company's previously defined objectives.[9] For example, risky events include increases in the prices of raw materials, an explosion at a factory, or a loss of customers to a competitor. To prevent overlooking risky events, ERM systems typically define categories and then identify the potential events within those categories. We will take a much closer look at risk categories later.

COMPONENT 4: RISK ASSESSMENT

After identifying a risk, a company should assess the risk. We will describe risk assessment in more detail later, but it always includes estimating both the probability that the event will occur and the resulting impact on the company's objectives. For example, an event might be an increase in interest rates, which would affect a company's cost when it issues debt. To assess this risk, the company would begin by forecasting the probabilities of different interest rates at the time it plans to issue the debt, and then estimate the cost of issuing debt at the different interest rates. As another example, an event might be a fire at a warehouse. In this case, a company would estimate the probability of a fire and the resulting cost. The insurance industry often uses the terms *loss frequency* and *loss severity* (the dollar value of each loss) for these concepts.

COMPONENT 5: RISK RESPONSE

After identifying and assessing a risky event, the next steps are to choose a response to the risk and implement that choice. There are several different types of responses, including the following.

Totally Avoid the Activity That Gives Rise to the Risk For example, a company might discontinue a product or service line because the risks outweigh the rewards. This often is the case with pharmaceutical products that have potentially harmful side effects or global expansion into countries with civil unrest.

[9]COSO defines risk as an event that negatively affects an objective, and an opportunity as an event that can positively affect an objective. We don't make that distinction—we define risk as uncertainty, which can result in positive or negative outcomes.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Reduce the Probability of Occurrence of an Adverse Event The expected loss arising from any risk is a function of both the probability of occurrence and the dollar loss if the adverse event occurs. In some instances, it is possible to reduce the probability that an adverse event will occur. For example, the probability that a fire will occur can be reduced by instituting a fire prevention program, by replacing old electrical wiring, and by using fire-resistant materials in areas with the greatest fire potential.

Reduce the Magnitude of the Loss Associated with an Adverse Event In some instances, companies can take actions to reduce losses even if the event occurs. Continuing with the previous example, the dollar cost associated with a fire can be reduced by such actions as installing sprinkler systems, designing facilities with self-contained fire zones, and locating facilities close to a fire station.

Transfer the Risk to an Insurance Company Often, it is advantageous to insure against risk by transferring it to an insurance company. Even though an insured item's expected loss is the same for its owner and for the insurance company, the insurance company benefits from diversification. For example, an insurance company might provide coverage for tractors, harvesters, and other types of agricultural equipment, which often cost several hundred thousand dollars or more. If the insurance company has a large number of customers, it can predict quite accurately the amounts it will pay in claims and then can set premiums high enough to pay the claims and provide the return required by its investors. In addition, insurance companies can themselves insure parts of their risk by purchasing reinsurance from another insurance company. Therefore, the potential loss of a harvester might be quite risky to a farmer, but it may not be risky to a large insurance company.

However, just because something can be insured does not mean that a company should insure it. In many instances, it might be better for the company to *self-insure*, which means bearing the risk directly rather than paying another party to bear it. In fact, many large companies choose to self-insure, or to insure only the part of an asset's loss that exceeds a certain amount, which is equivalent to an individual who has a large deductible on car or home insurance.

Insurance typically excludes acts of war or terrorism, but this became a major issue after the September 11, 2001, attacks on the World Trade Center and the Pentagon. Unless possible terrorist targets—including large malls, office buildings, oil refineries, airlines, and ships—can be insured against attacks, lenders may refuse to provide mortgage financing, and that would crimp the economy. Private insurance companies are reluctant to insure these projects, at least without charging prohibitive premiums, so the federal government has been asked to step in and provide terrorist insurance. However, losses due to terrorist attacks are potentially so large that they could bankrupt even strong insurance companies. Therefore, Congress passed the Terrorism Risk Insurance Act (TRIA) in 2002 and has extended it until 2020. Under the TRIA, the federal government and private insurers share the cost of benefits paid on insured losses caused by terrorists.

Transfer the Function That Produces the Risk to a Third Party For example, suppose a furniture manufacturer is concerned about potential liabilities arising from its ownership of a fleet of trucks used to transfer products from its manufacturing plant to various points across the country. One way to eliminate this risk would be to contract with a trucking company to do the shipping, thus passing the risks to a third party.

Share or Eliminate the Risk by Using Derivative Contracts Many companies use derivative contracts to reduce or eliminate an event's risk. For example, a cereal company may use corn or wheat futures to hedge against increases in grain prices. Similarly, financial derivatives can be used to reduce risks that arise from changes in interest rates

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

and exchange rates. As we will describe later, the risk doesn't disappear—it is just taken on by the other party in the derivative contract.

Accept the Risk In some instances, a company will decide to accept a risk because the expected benefits are greater than the expected costs and because the risk doesn't exceed the company's risk appetite. Indeed, accepting risk is the nature of most businesses—if they were riskless, then investors would expect to receive a return only equal to the risk-free rate. Also, some stand-alone risks may be quite large, but they may not contribute much to the total corporate risk if they are not highly correlated with the company's other risks.

COMPONENTS 6, 7, AND 8: CONTROL ACTIVITIES, INFORMATION AND COMMUNICATION, AND MONITORING

The last three components focus on ensuring that risky events are in fact being treated according to the responses that were previously chosen—it doesn't do much good to develop strategies and tactics if employees don't follow them! For example, a single rogue trader lost €4.9 billion in 2008 at the French bank Societe Generale, and another lost £1.5 billion in 2011 at the London branch of UBS (headquartered in Switzerland).

SELF-TEST

Define a risk event.

What are the two stages in risk assessment?

Describe some possible risk responses.

Should a firm insure itself against all of the insurable risks it faces? Explain.

23-4 Categories of Risk Events

Before addressing alternative risk responses to specific risk events, it will be helpful to describe ways to categorize risk.

23-4a Major Categories

Following is a typical list of major categories that are representative of those at several organizations.[10]

1. *Strategy and reputation.* A company's strategic choices simultaneously influence and respond to its competitors' actions, corporate social responsibilities, the public's perception of its activities, and its reputation among suppliers, peers, and customers. ERM addresses the risk inherent in these strategic choices.
2. *Control and compliance.* This category includes risk events related to regulatory requirements, litigation risks, intellectual property rights, reporting accuracy, and internal control systems.

[10]To see the way that several organizations have categorized risk and the ways that surveyors categorize risk, see the following: Mark L. Frigo and Hans Læssøe, "Strategic Risk Management at the LEGO Group," *Strategic Finance*, February 2012, pp. 27–35; Henri Servaes, Ane Tamayo, and Peter Tufano, "The Theory and Practice of Corporate Risk Management," *Journal of Applied Corporate Finance*, Fall 2009, pp. 60–78; Celina Rogers, *The Risk Management Imperative* (Boston: CFO Publishing LLC, 2010), **http://secure.cfo.com/whitepapers/index.cfm/download/14521624;** Casualty Actuarial Society, *Overview of Risk Management,* 2003, **https://www.casact.org/area/erm/overview.pdf** and the sources cited in footnote 12.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

3. *Hazards.* These include fires, floods, riots, acts of terrorism, and other natural or man-made disasters. Notice that hazards only have negative outcomes—an earthquake might destroy a factory, but it isn't going to build one.
4. *Human resources.* Success often depends upon a company's employees. ERM addresses risk events related to employees, including recruiting, succession planning, employee health, and employee safety.
5. *Operations.* A company's operations include supply chains, manufacturing facilities, existing product lines, and business processes. Risk events include supply chain disruptions, equipment failures, product recalls, and changes in customer demand.
6. *Technology.* Technology changes rapidly and is a major source of risk, including risk events related to innovations, technological failures, and IT reliability and security.
7. *Financial management.* This category includes risk events related to: (1) foreign exchange risk, (2) commodity price risk, (3) interest rate risk, (4) project selection risk (including major capital expenditures, mergers, and acquisitions), (5) liquidity risk, (6) customer credit risk, and (7) portfolio risk (the risk that a portfolio of financial assets will decrease in value). For the remainder of the chapter, we will focus on the risk events related to financial management, but first we need to describe several other ways to think about risk.

23-4b Dimensions of Risk

Sometimes it is helpful to think about risk events based on different dimensions. For example, several risk management systems classify risk by whether it is driven by external forces or by internal decisions and activities. This is especially helpful in risk identification because it forces managers to look at a broader range of risk events.

Sometimes it is useful to classify risk by whether it is a pure risk that only has a downside (e.g., a hazard, such as a fire) or a speculative risk that has potential positive as well as negative outcomes (e.g., the exchange rate between dollars and euros can go up or down, which would have a big impact on the cash flows of U.S. importers). Most pure risks can be reduced or eliminated with insurance products.

When choosing among different risk responses, it is helpful to determine whether the source of risk is linear or nonlinear. For example, consider an agricultural company with access to a low-cost source of water for irrigation. The company grows corn and can predict its costs and the size of its harvest, but it is exposed to volatility in the price of corn. Notice that this is a linear risk—the company loses money when prices are low and makes money when they are high. We discuss the details later, but the company can enter into derivative contracts that provide positive cash flows when prices are low but create negative cash flows when prices are high. The derivative also has a linear payout, but its payouts are opposite those of the company. The combination of the company's internally generated cash flows from the harvest and its externally generated cash flows from the derivative can reduce or eliminate the company's risk.

In contrast, consider a company in the oil exploration and extraction industry.[11] The company will incur fixed costs and negative cash flows associated with continuing operations when oil prices are too low to justify additional exploration. When oil prices are high, the company incurs fixed costs and also variable costs associated with

[11]See Kenneth A. Froot, David S. Scharfstein, and Jeremy Stein, "A Framework for Risk Management," *Journal of Applied Corporate Finance*, Fall 1994, pp. 22–32; also see the paper by Servais et al., cited in footnote 14.

expanded exploration and extraction. However, when oil prices are high, the company will generate enough positive cash flow to cover its fixed costs and also the new variable costs associated with the additional exploration and extraction. Therefore, the company is exposed to nonlinear risk—it needs additional cash flow to support its ongoing operations only when oil prices are low but not when prices are high. In this situation, the company might be willing to buy a derivative that pays out only when oil prices are low. In other words, the company reduces its nonlinear risk with a nonlinear hedging strategy.

SELF-TEST

List and define the different major categories of risk events.

Should a firm insure itself against all of the insurable risks it faces? Explain.

Explain the difference between a linear risk and a nonlinear risk.

23-5 Foreign Exchange (FX) Risk

Foreign exchange (FX) risk occurs when a company's cash flows are affected by changes in currency exchange rates. This can occur if a company imports materials from other countries or sells its products in other countries. Some smaller companies manage FX risk for each transaction, but most large companies aggregate their transactions and manage their exposures centrally. For example, if one division is selling goods denominated in Canadian dollars and another division is purchasing goods denominated in Canadian dollars, the company would net out the two transactions and just manage any remaining exposure.

The primary tool used to manage FX risk is a **forward contract**, which is an agreement in which one party agrees to buy an item at a specific price on a specific future date and another party agrees to sell the item at the agreed-upon terms. *Goods are actually delivered under forward contracts.* In the case of foreign exchange, the goods are the amount of foreign currency specified in the contract, paid for with the other currency specified in the contract.

Historically, FX trading has been directly between two parties using customized contracts with unique amounts and dates and no central market. This requires that both parties be morally and financially strong to minimize the danger that one party will default on the contract—this is called **counterparty risk**. In such contracts, major banks often act as counterparties for their customers. For example, a bank might agree to buy euros in 30 days at a price of 1.24 dollars per euro from one customer and agree to sell euros in 30 days at a rate of 1.25 dollars per euro to another customer. Depending on the change in the euro exchange rate, the bank will make money on one of the contracts and lose money on the other, netting only the spread on the difference in prices. This matching of contracts allows banks to reduce their net exposure to exchange rate volatility, but the bank is still exposed to counterparty risk from the customers.

The failure to manage counterparty risk was one of the causes of the 2007 global financial crisis. For example, Lehman Brothers was a counterparty to many other financial institutions in a variety of derivative contracts, so Lehman's failure caused distress at financial institutions throughout the world. In response to this and other causes of the financial crisis, the Dodd-Frank Consumer Protection Act was passed in 2010. One of its provisions required the Commodities and Futures Trading Commission (CFTC) to establish, among other things, a mechanism for centralized clearing of foreign exchange

derivatives contracts, such as forward contracts. The CME Group is one company that provides this clearing function in the United States and acts as the counterparty to all trades that it clears. As of mid-2015, the CME Group is able to clear 38 cash-settled forward contracts involving 33 different currencies.[12]

Foreign exchange transactions are a big business. Contracts are based on the total amount of currency to be delivered at expiration, which is called the **notional value**. At the beginning of 2015, the notional value of over-the-counter FX derivatives was about $76 trillion![13] The total is even larger if customized FX contracts between two parties are considered.

To illustrate how foreign exchange contracts are used, suppose GE arranges to buy electric motors from a European manufacturer on terms that call for GE to pay 10 million euros in 180 days. GE would not want to give up the free trade credit, but if the euro appreciated against the dollar during the next 6 months, then the dollar cost of the 10 million euros would rise. GE could hedge the transaction by buying a forward contract under which it agreed to buy the 10 million euros in 180 days at a fixed dollar price, which would lock in the dollar cost of the motors. This transaction would probably be conducted through a money center bank, which would try to find a European company that needed dollars in 6 months.

Explain how a company can use forward contracts to eliminate FX risk.

What is counterparty risk?

23-6 Commodity Price Risk

WWW

See the CME Group's Web site, **www.cmegroup.com**, *for a wealth of information on the operation and history of the exchange.*

Many companies use or produce commodities, including agricultural products, energy, metals, and lumber. Because commodity prices can be quite volatile, many companies manage their exposure to commodity price risk. Before describing specific ways to manage commodity price risk, we begin with a brief overview of futures markets in the United States to illustrate some key concepts.

23-6a An Overview of Futures Markets

As we noted earlier, Midwest farmers in the early 1800s were concerned about the price they would receive for their wheat when they sold it in the fall, and millers were concerned about the price they would have to pay. Each party soon realized that the risks they faced could be reduced if they established a price earlier in the year. Accordingly, mill agents began going out to the Wheat Belt with contracts that called for the farmers to deliver grain at a predetermined price, and both parties benefited from the transaction in the sense that their risks were reduced. The farmers could concentrate on

[12]When a traditional forward for delivery contract expires, the two currencies are exchanged. In a cash-settled forward contract, however, the currencies are never exchanged. Rather, the difference between the contract price and the spot price at expiration is converted to U.S. dollars at the prevailing spot price and then these dollars are paid or received. The clearinghouse would require some form of collateral to reduce the risk that one of the parties didn't pay. In addition, cash-settled forward contracts can be "marked to market" every day like a futures contract, and this further reduces the clearinghouse's risk. See the CME Group's Web site, **www.CMEGroup.com**, for more information on their clearing mechanism and the products it clears.

[13]See the Bank for International Settlements, **www.bis.org/statistics/derstats.htm.**

growing their crop without worrying about the price of grain, and the millers could concentrate on their milling operations.

These early agreements were between two parties who arranged the transactions themselves. Soon, though, intermediaries came into the picture. The Chicago Board of Trade, founded in 1848, was an early marketplace where *futures dealers* helped make a market in futures contracts.

A **futures contract** is similar to a forward contract in that two parties are involved, with one party taking a long position (which obligates the party to buy the underlying asset) and the other party taking a short position (which obligates the party to sell the asset). However, there are three key differences. First, futures contracts are **marked-to-market** on a daily basis, meaning that gains and losses are recognized daily and money must be put up to cover losses. This greatly reduces the risk of default that exists with forward contracts because daily price changes are usually smaller than the cumulative change over the contract's life. For example, if a corn futures contract has a price of $4.00 per bushel and the price goes up to $4.10 the next day, a party with a short position must pay the $0.10 difference, and a party with a long position would receive the difference. This marking-to-market occurs daily until the delivery date. To see that this procedure does in fact lock in the price, suppose that the price doesn't change again. On the delivery date, the party with the short position would sell corn at the current price of $4.10. Because the short seller had already paid $0.10 from daily marking-to-market, the short seller's net cash flow is $4.00. The party with the long position would have to buy corn at the current price of $4.10, but because the purchaser had already received $0.10 from cumulative daily marking-to-market, the net purchase price would be $4.00.

The second major difference between a forward contract and a futures contract is that physical delivery of the underlying asset in a futures contract is virtually never taken—the two parties simply settle up with cash for the difference between the contracted price and the actual price on the expiration date. The third difference is that futures contracts are generally standardized instruments that are traded on exchanges, whereas forward contracts are usually tailor-made, negotiated between two parties, and not traded after they have been signed.

The needs of farmers and millers allowed a **natural hedge**, defined as a situation in which aggregate risk can be reduced by derivatives transactions between two parties. Natural hedges occur when futures are traded between cotton farmers and cotton mills, copper mines and copper fabricators, importers and foreign manufacturers for currency exchange rates, electric utilities and coal mines, and oil producers and oil users. In such situations, hedging reduces aggregate risk and thus benefits the economy.

There are two basic types of hedges: (1) **long hedges**, in which futures contracts are *bought* (obligating the hedger to purchase the underlying asset), providing protection against price increases, and (2) **short hedges**, where a firm or individual *sells* futures contracts (obligating the hedger to sell the underlying asset), providing protection against falling prices.

Not all participants in the futures markets are hedgers. **Speculation** involves betting on future price movements, and futures are used instead of the commodities because of the leverage inherent in the contract. For example, a speculator might buy corn for $4 a bushel. If corn goes up to $4.40, the speculator has a 10% return (assuming rats don't eat the corn before it can be sold).

Now consider a speculator who takes a short position in a futures contract for 5,000 bushels at $4 per bushel. The exchange requires an investor to put up a **margin requirement** to ensure that the investor will not renege on the daily marking-to-market. However, the

margin is quite small relative to the size of a contract—the margin is only $1,100, but the total amount of corn is valued at $20,000 = $4(5,000).[14] If the price goes up to $4.40, the profit is $2,000 = ($4.40 − $4.00)(5,000). The rate of return on the invested margin is 82% = ($2,000 − $1,100)/$1,100. The 82% return on the futures contract is much greater than the 10% return on the underlying asset. Of course, any losses on the contract also would be magnified.

At first blush, one might think that the appearance of speculators would increase risk, but this is not necessarily true. Speculators add capital and players to the market. Thus, to the extent that speculators broaden the market and make hedging possible, they help decrease risk for those who seek to avoid it. Unlike the natural hedge, however, risk is not eliminated. Instead, it is transferred from the hedgers to the speculators.

Today, futures contracts are available on hundreds of real and financial assets traded on dozens of U.S. and international exchanges, the largest of which are the Chicago Board of Trade (CBOT) and the Chicago Mercantile Exchange (CME), both of which are now part of the CME Group. Futures contracts are divided into two classes, **commodity futures** and **financial futures**. Commodity futures include oil, various grains, oilseeds, livestock, meats, fibers, metals, and wood. Financial futures, which were first traded in 1975, include Treasury bills, notes, bonds, certificates of deposit, Eurodollar deposits, foreign currencies, and stock indexes. We describe how financial futures can reduce interest rate risk in a later section.

23-6b Using Futures Contracts to Reduce Commodity Price Exposure

We will illustrate commodity hedging at Porter Electronics, which uses large quantities of copper and several precious metals in its manufacturing operations. Suppose that in May 2016, Porter foresaw a need for 100,000 pounds of copper in March 2017 for use in fulfilling a fixed-price contract to supply solar power cells to the U.S. government. The spot price of copper in May is $4.08. Therefore, it would cost Porter $408,000 to purchase the copper in March if the prices don't change: 100,000($4.80) = $408,000. However, Porter's managers are concerned that a strike by Chilean copper miners might occur, which would raise the price of copper in world markets and reduce Porter's expected profit.

Porter could go ahead and buy the copper it will need to fulfill the contract, but it would have to borrow money to pay for the copper and then pay for storage. As an alternative, Porter could hedge against increasing copper prices in the futures market. COMEX, a division of The New York Commodity Exchange, trades standard copper futures contracts of 25,000 pounds each. Thus, Porter could buy four contracts (go long) for delivery in March 2017. Suppose these contracts were trading in May 2016 for about $4.10 per pound.

What happens to Porter's cash flows if copper prices rise to $4.30 by the delivery date? Porter would have to spend $430,000 to buy the copper it needs. However, Porter would

[14]The CME requires that an investor make an initial deposit at the time the investor takes a position in a contract. The dollar value of the initial margin might decline if the investor uses some of it to pay for daily marking-to-market. However, the investor must not let the amount on deposit drop below a specified amount, which is called the maintenance margin. The CME specifies the maintenance margin for each contract. For example, if you go to the CME Web site (**www.cmegroup.com**) and search for a contract, such as corn futures, you will be directed to a page with information about the contract, with an option to find the maintenance margin. For corn, it is $1,000 in 2015. For hedgers, the initial margin is set at 100% of the maintenance margin; for speculators, the initial margin is set at 110% of the maintenance margin (see **www.cmegroup.com/clearing/margins/initial-margin-requirements.html**). These margins requirement change over time as the value of the underlying commodity changes. For example, the corn margin was $3,750 in July of 2012, when corn spot prices where near record highs.

have made a profit on its futures contracts of \$0.20 per pound (\$4.30 − \$4.10 = \$0.20).[15] With contracts for 100,000 pounds, Porter's profit would be \$20,000. Therefore, Porter's net cost to purchase the copper would be equal to the \$430,000 it actually paid minus the \$20,000 profit on the contract, which is a net cost of \$410,000.

Now suppose copper prices fell to \$4.00 per pound. Porter would have to pay \$400,000 for the copper, but would have lost \$10,000 on the futures contract: (\$4.00 − \$4.10)(100,000) = −\$10,000. Porter's net cost would have been equal to the \$400,000 it paid for the copper minus the loss of \$10,000, for a net cost of \$410,000.

As this example shows, hedging in the copper futures market locks in Porter's net cost of raw materials at \$410,000, eliminating any exposure to changes in copper prices. However, if copper prices had remained at their original spot price of \$4.08, Porter would have paid only \$408,000 for copper instead of its net cost of \$410,000 with the hedge. Therefore, the hedge came with a cost: Porter locked in the price it paid for copper, but that fixed price might have been higher than the expected price.

Many other companies, such as Alcoa with aluminum and Archer Daniels Midland with grains, routinely use the futures markets to reduce the risks associated with price volatility.

23-6c Options on Futures

Futures contracts and options are similar to one another—so similar that people often confuse the two. Therefore, it is useful to compare the two instruments. A *futures contract* is a definite agreement on the part of one party to buy something on a specific date and at a specific price, and the other party agrees to sell on the same terms. No matter how low or how high the price goes, the two parties must settle the contract at the agreed-upon price and the losses of one party must exactly equal to the gains of the other. In addition, a dollar increase in the futures price has exactly the opposite effect of a dollar decrease in the futures price. A hedge constructed using futures contracts is called a **symmetric hedge** because of this feature—the payoff from an increase in the futures price is exactly opposite the payoff from a decrease in the futures price. For this reason, symmetric hedges are typically used to provide a fixed transaction price at some date in the future and are ideal for managing a risk that is linear.

For example, suppose an agricultural company has access to a source of low-cost water for irrigation. The company can predict its costs and the size of its harvest but is exposed to price risk. The company could sell futures contracts (take a short position, which obligates it to sell corn) for delivery when the corn is harvested in 6 months. If the corn price (and hence the corn futures price) decreases over the 6 months, then the company will receive less when selling the corn but will make up the difference when closing out the futures contract. If instead the corn price increases, then the company will make more money when selling the corn in 6 months but will lose money when closing out the futures contract. In this way the ending value of the position doesn't depend on the corn price in 6 months, and so the amount received for selling the corn in 6 months is locked in.

An *option*, on the other hand, gives someone the right to buy (call) or sell (put) an asset, but the holder of the option does not have to complete the transaction. The payoff from a hedge constructed using options will be different from a futures hedge because of this option feature. As discussed in Chapter 8, the payoff from a call option increases as the price of the underlying asset increases, but if the underlying asset price decreases, then the most the option holder can lose is the amount invested in the option. That is, upside gains are unlimited but downside losses are capped at the amount invested in the option. For this reason, an option is said to create an **asymmetric hedge**—it hedges price changes in one direction more than price changes in the other. As such, options are ideal for managing nonlinear risks.

[15]To focus the example on the primary impact of hedging, we have ignored daily marking-to-market.

For example, suppose the agricultural company did not have access to irrigation but operated many farms in different states. A widespread drought would reduce the size of the harvest but probably would cause the price of corn to increase due to the lower supply. If this happened, the company's revenues would fall but would not be eliminated—the higher corn price would partially compensate for the smaller harvest. This means the company faces nonlinear risk with respect to corn prices. Instead of going long in a futures contract, the company might buy a put option on a corn futures contract, giving the company the right to sell a futures contract at a fixed price. If the price of corn decreased, the value of the put option would increase, and the profits on the option would offset the loss from selling the corn at the lower price. However, if corn prices increased, then the investor would let the put option expire and simply sell its smaller harvest at the higher price.

SELF-TEST

How does a futures contract differ from a forward contract?

What is a "natural hedge"? Give some examples of natural hedges.

Suppose a company knows the quantity of a commodity that it will produce. Describe how it might hedge using a futures contract.

23-7 Interest Rate Risk

Interest rates can be quite volatile, exposing a company to interest rate risk, especially if the company is planning to issue debt or if the company has floating-rate debt. The following sections describe these two situations.

23-7a Using Futures Contracts to Manage the Risk of Debt Issuances

To illustrate, assume that it is May and that Carson Foods is considering a plan to issue $10,000,000 of 20-year bonds in September to finance a capital expenditure program. The interest rate would be 9% paid semiannually if the bonds were issued today. However, the market interest rate might be higher when the bonds are actually issued. Carson would have to issue the bonds with a higher coupon rate than expected, causing Carson's financing costs to increase. Carson can protect itself against a rise in rates by hedging in the futures market using an interest rate futures contract.

INTEREST RATES FUTURES

To illustrate how interest rate futures work, consider the CBOT's contract on Treasury bonds. The basic contract is for $100,000 of a hypothetical 6% coupon, semiannual payment Treasury bond with 20 years to maturity.[16] Table 23-1 shows illustrative quotes for Treasury bond futures.

[16]The coupon rate on the hypothetical bond was changed to 6% from 8% in March 2000. The CBOT contract doesn't specify a 20-year bond but instead allows delivery of any noncallable bond with a remaining maturity greater than 15 years (or callable bond that is not callable for at least 15 years) and less than 25 years. Rather than simply deliver a bond, which might have an interest rate other than 6%, the actual bond price is adjusted by a conversion factor to make it equivalent to a 6% bond that is trading at par. Because the average maturity of bonds that are eligible for delivery is about 20 years, we use a 20-year maturity for the hypothetical bond in the futures contract. For even longer maturity hedging, the CBOT also has the Ultra T-Bond contract, which allows for delivery of a Treasury bond of at least 25 years to maturity.

TABLE 23-1
Example of Futures Prices (Treasury Bonds: $100,000; Pts. 32nds of 100%) in May

Delivery Month/Year (1)	Settle (2)	Change (3)	Open (4)	High (5)	Low (6)	Estimated Volume (7)	Open Interest (8)
Jun-17	128'12	0'14	128'06	129'11	127'30	500,000	640,000
Sep-17	127'11	0'15	127'01	127'31	126'28	300,000	95,000
Dec-17	126'16	0'17	126'16	126'16	126'16	0	50

The first column of Table 23-1 shows the delivery month and year. Column 2 shows the last price of the day, also called the *settlement* price, and the next column shows the change in price from the previous day. For example, the settlement price for the September contract, 127'11, means 127 plus 11/32, or 127.343750%, of par. The change was 0'15, which means the September 2017 contract's last price of the day was 15/32 higher than the previous day's last trade, which must have been at 126'28. The next three columns show the opening, high, and low prices for the day. Column 7 shows the day's estimated trading volume. Notice that most of the trading occurs in the contract with the nearest delivery date. Finally, Column 8 shows the "open interest," which is the number of contracts outstanding.

To illustrate, we focus on the Treasury bonds for September delivery. The settlement price was 127.343750% of the $100,000 contract value. Thus, the price at which one could buy $100,000 face value of 6%, 20-year Treasury bonds to be delivered in December was 127.343750%($100,000) = $127,343.75.

The contract price increased by 15/32 of 1% of $100,000 from the previous day's price, so if you had bought the contract yesterday, you would have made $468.75 = (15/32)(0.01)($100,000). There were 95,000 contracts outstanding, representing a total value of about 95,000($127,343.75) = $12,097,656.

resource

*See **Ch23 Tool Kit.xlsx** on the textbook's Web site for all calculations.*

Note that the contract increased by 15/32 of a percent on this particular day. Why would the value of the bond futures contract increase? Bond prices increase when interest rates fall, so interest rates must have fallen on that day. Moreover, we can calculate the implied rate inherent in the futures price. Recall that the contract relates to a hypothetical 20-year, semiannual payment, 6% coupon bond. The settlement price was 127.343750% of par, so a $1,000 par bond would have a price of 127.343750%($1,000) = $1,273.4375. We can solve for r_d by using the following equation:

$$\sum_{t=1}^{40} \frac{\$30}{(1 + r_d/2)^t} + \frac{\$1,000}{(1 + r_d/2)^{40}} = \$1,273.4375$$

Using *Excel* or a financial calculator, input N = 40, PV = −1273.4375, PMT = 30, and FV = 1000; then solve for I/YR = 2.0004%. This is the semiannual rate, which is equivalent to a nominal annual rate of 4.0007%, or approximately 4.00%.

The previous day's last (settlement) price was 126'28, or 126.87500%, for a bond price of $1,268.7500 = 126.87500($1,000). Setting N = 40, PV = −1268.7500, PMT = 30, and FV = 1000 and then solving for I/YR = 2.0150 implies an annual yield of 4.0300%, or approximately 4.03%. Therefore, interest rates fell from 4.03% to 4.00%. This decline in rates was only 0.03 percentage points, but that was enough to increase the value of the contract by $468.75. Rather than discuss changes in percentage points, financial traders use **basis points**, with 100 basis points equal to 1 percentage point. Therefore, the decline in rates was 3 basis points.

At the time of the quotes in Table 23-1, which was May, the yield on a 20-year T-bond was about 3.90%. But as we just calculated, the implied yield on the September futures

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. contract was about 4.00%. The September yield reflects investors' beliefs in May as to what the interest rate level will be in September: The marginal trader in the futures market is predicting a 10-basis-point increase in yields between May and September. That prediction could, of course, turn out to be incorrect.

For example, suppose that the implied yields in the futures market had fallen by 50 basis points from May to August—say, from 4.00% to 3.50%. Inputting N = 40, I/YR = 3.5/2 = 1.75, PMT = 30, and FV = 1000 and then solving for PV = −1,357.4279 shows that the September contract would be worth about $1,357.4279 per bond in August if implied yields fell by 50 basis points. Thus, the contract's value would have increased from $127,343.75 to $135,742.79, a gain of about $8,399: $135,742.79 − $127,343.75 ≈ $8,399.

HEDGING WITH TREASURY BOND FUTURES CONTRACTS

Recall that Carson Foods plans to issue $10,000,000 of 9% semiannual 20-year bonds in September and would like to protect itself from a possible increase in interest rates by using T-bond futures contracts. Rising interest rates cause bond prices to fall, and thus decrease the value of bond futures contracts. Therefore, Carson can guard against an *increase* in interest rates by taking a short position on a T-bond futures contract—if rates go up, Carson will receive a cash flow from the futures contract equal to the original futures price less the now-lower futures price.

resource

See ***Ch23 Tool Kit.xlsx*** *on the textbook's Web site for all calculations.*

Carson would choose a futures contract on the security most similar to the one it plans to issue, long-term bonds, and so would use the September Treasury bond futures. In the previous section, we calculated the price of a contract, which was $127,343.75. Because Carson plans to issue $10,000,000 of bonds and because each contract is worth $127,343.75, Carson will sell $10,000,000/$127,343.75 = 78.528 ≈ 79 contracts for delivery in September.[17] The total value of the contracts is 79($127,343.75) = $10,060,156, which is very close to the value of the bonds Carson wants to issue.

Now suppose that in September, when Carson issues its bonds, renewed fears of inflation push interest rates up by 100 basis points. What would the bond proceeds be if Carson still tried to issue 9% coupon bonds when the market requires a 10% rate of return? We can find the total value of the offering with a financial calculator, inputting N = 40, I/YR = 5, PMT = −450000, and FV = −10000000 and then solving for PV = 9,142,046. Therefore, bonds with a 9% coupon, based upon its original plans, would bring proceeds of only $9,142,046, because investors now require a 10% return. Because Carson would have to issue $10 million worth of bonds at a 10% rate, Carson's proceeds would be less than expected: $857,954 = $10,000,000 − $9,142,046 as a result of delaying the financing. Therefore, Carson would have to issue additional bonds to raise the required $10,000,000. In other words, the increase in interest rates resulted in cost to Carson of $857,954.

Alternatively, we can estimate Carson's cost of delaying by calculating the present value of the incremental payments Carson must make. The increase in interest rates from 9% to 10% would cause the semiannual coupon payments to go up from $45 to $50 on a per-bond basis. For 10,000 bonds, the total incremental semiannual coupon payments are $50,000 = ($50 − $45)(10,000). We can find the present value of these incremental payments by inputting N = 40, I/YR = 5, PMT = −50000, and FV = 0 and then solving for PV = −857954 = −$857,954, which is the same cost found by the first method. Intuitively, this is because the first method identifies the difference between an asset's par value and its

[17]Carson will have to put up a margin and pay brokerage commissions. To keep the example focused on the primary issue, which is the impact of changing interest rates, we will ignore margins and commissions.

market value given a change in interest rates. This difference can be thought of as the extra amount of value that would need to be added to bring the market value up to par. One way to add value would be to increase the payments, which is what the second approach does.

Either way, Carson incurs a cost of $857,954 due to the increase in rates. However, the increase in interest rates would also bring about a change in the value of Carson's short position in the futures contract. When interest rates increase, the value of the futures contract will fall. If the interest rate on the futures contract also increased by the same full percentage point, from 4.0007% to 5.0007%, then the new contract value can be found by inputting N = 40, I/YR = 5.0007/2 = 2.50035, PMT = −3000, and FV = −100000 and then solving for PV = 112,541.86 per contract. With 79 contracts, the total value of the position is thus $8,890,806.94 = 79($112,541.86). Carson would then close its position in the futures market by repurchasing for $8,890,806.94 the contracts that it earlier sold for $10,060,156.00, giving it a profit of $1,169,349.06.

Thus, Carson would offset the loss on the bond issue. In fact, in our example Carson more than offsets the loss, pocketing an additional $311,395.06 = $1,169,349.06 − $857,954.[18] Of course, if interest rates had fallen, then Carson would have lost on its futures position, but this loss would have been offset because Carson could now sell its bonds with a lower coupon.

If futures contracts existed on Carson's own debt and if interest rates moved identically in the spot and futures markets, then the firm could construct a **perfect hedge** in which gains on the futures contract would exactly offset losses on the bonds. In reality, it is virtually impossible to construct perfect hedges, because in most cases the underlying asset is not identical to the futures asset; and even when the assets are identical, prices (and interest rates) may not move exactly together in the spot and futures markets.[19]

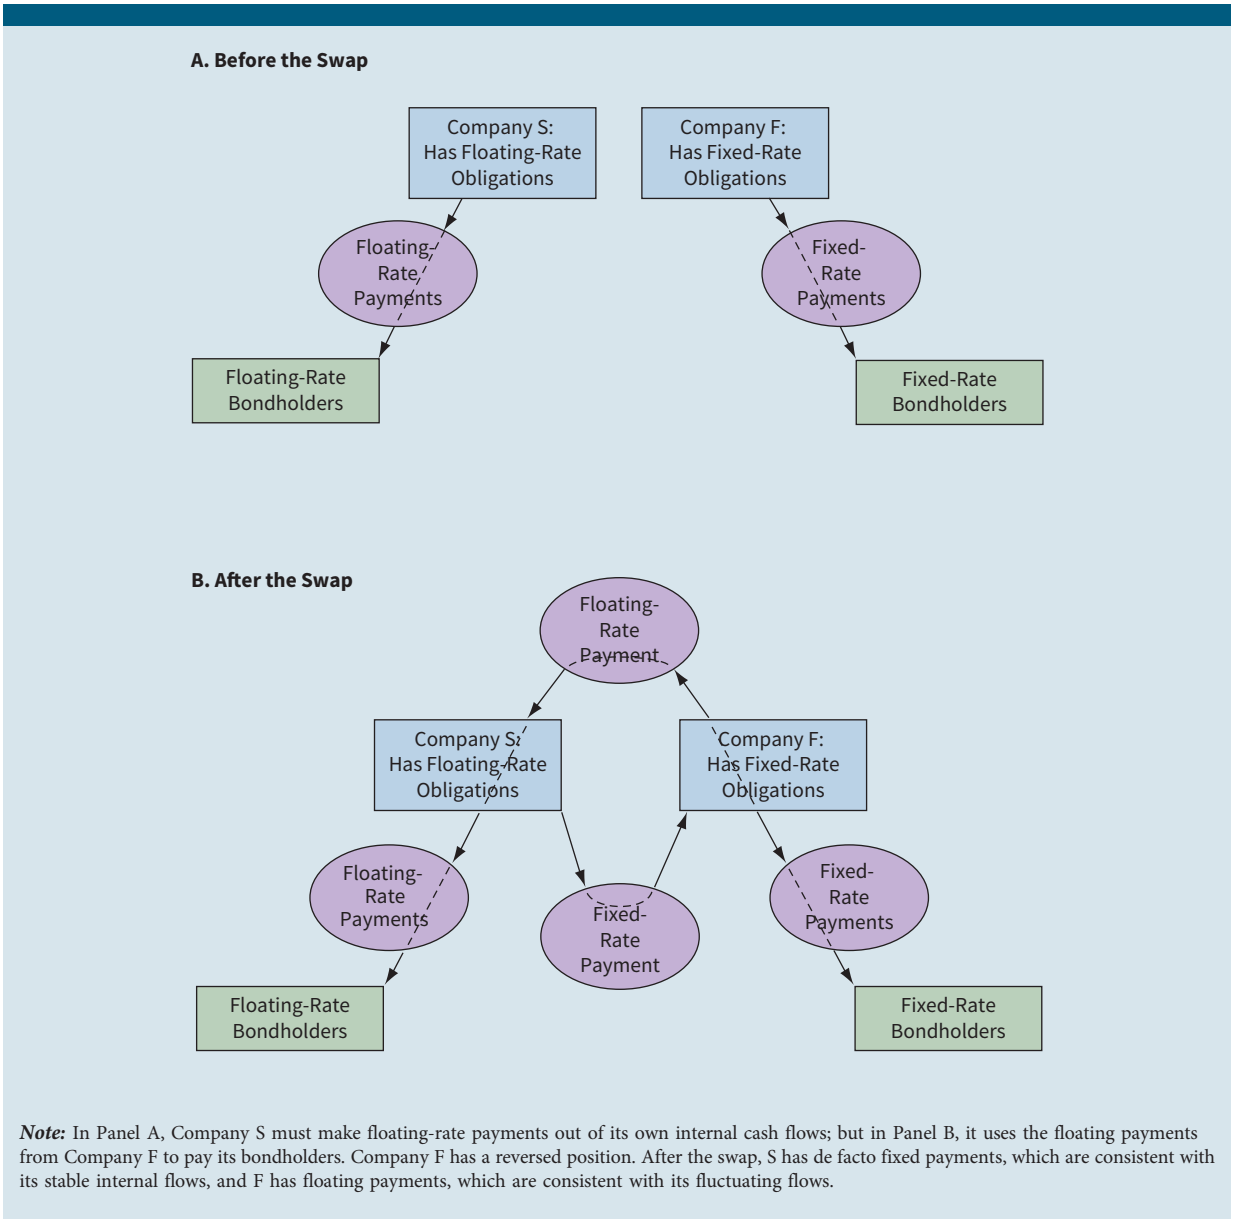
Observe also that if Carson had been planning an equity offering and if its stock tended to move fairly closely with one of the stock indexes, then the company could have hedged against falling stock prices by selling the index future. Even better, if options on Carson's stock were traded in the options market, then it could use options rather than futures to hedge against falling stock prices.

The futures and options markets permit flexibility in the timing of financial transactions: The firm can be protected, at least partially, against changes that occur between the time a decision is reached and the time the transaction is completed. However, this protection has a cost—the firm must pay commissions. Whether or not the protection is worth the cost is a matter of judgment. The decision to hedge also depends on management's risk aversion and on the company's strength and ability to assume the risk in question.[20]

---

[18]Carson would have to pay taxes on the profit from the futures contract, so the after-tax value of the futures transaction can be found by multiplying the pre-tax profit by (1 – T). However, Carson would get to deduct the larger additional coupon payments from its income. To find the present value of the after-tax additional coupon payments, we multiply the additional pre-tax coupons by (1 – T) and calculate the present value. This gives the same result as first finding the present value of the additional pre-tax coupons and then multiplying the present value by (1 – T). In other words, the pre-tax cost of delaying and the pre-tax profit from the futures contract should be multiplied by (1 – T) to estimate the after-tax effectiveness of the hedge.

[19]In this example, Carson hedged a 20-year bond with a T-bond futures contract. Rather than simply matching on maturity, it would be more accurate to match on duration (see ***Web Extension 5C***, available on the textbook's Web site, for a discussion of duration). A matching duration in the futures contracts could be accomplished by taking positions in the T-bond futures contract and in another financial futures contract, such as the 10-Year Treasury note contract. Because Carson's bond had a 20-year maturity, matching on maturity instead of duration provided a good hedge. If Carson's bond had a different maturity, then it would be essential to match on duration.



[20]For additional insights into the use of financial futures for hedging, see Mark G. Castelino, Jack C. Francis, and Avner Wolf, "Cross-Hedging: Basis Risk and Choice of the Optimal Hedging Vehicle," *The Financial Review*, May 1991, pp. 179–210.

23-7b Using Interest Rate Swaps: Managing Floating versus Fixed Rates

Suppose that Company S has a 20-year, $100 million floating-rate bond outstanding and that Company F has a $100 million, 20-year, fixed-rate issue outstanding. Thus, each company has an obligation to make a stream of interest payments, but one payment stream is fixed while the other will vary as interest rates change in the future. This situation is shown in Panel A of Figure 23-1.

FIGURE 23-1
Cash Flows under a Swap

Note: In Panel A, Company S must make floating-rate payments out of its own internal cash flows; but in Panel B, it uses the floating payments from Company F to pay its bondholders. Company F has a reversed position. After the swap, S has de facto fixed payments, which are consistent with its stable internal flows, and F has floating payments, which are consistent with its fluctuating flows.

Now suppose that Company S has stable cash flows and wants to lock in its cost of debt. Company F has cash flows that fluctuate with the economy, rising when the economy is strong and falling when it is weak. Recognizing that interest rates also move up and down with the economy, Company F has concluded it would be better off with variable-rate debt. Suppose the companies agreed to swap their payment obligations. Panel B of Figure 23-1 shows that the net cash flows for Company S are at a fixed rate and those for Company F are based on a floating rate. Company S would now have to make fixed payments, which are consistent with its stable cash inflows, and Company F would have a floating obligation, which for it is less risky.

In practice, the two companies would not deal with one another directly; instead, each company would enter into a swap with a large bank. For example, a bank might offer to swap LIBOR for a fixed payment of 2.5%. In this example, Company S would pay the bank a fixed payment equal to 2.5% of the amount Company S borrowed at a floating rate and the bank would pay Company S an amount equal to the current LIBOR rate multiplied by the amount Company S borrowed. Company F would enter into a similar contract with a bank, except Company F would make a floating rate payment to the bank (based on LIBOR) and the bank would make a fixed payment to Company F. Of course, the bank will charge a fee for this service.

A **swap** is just what the name implies—two parties agree to swap something, generally obligations to make specified payment streams.

The previous example, which is an **interest rate swap**, illustrates how swaps can reduce risks by allowing each company to match the variability of its interest payments with that of its cash flows. However, there are also situations in which swaps can reduce both the risk and the effective cost of debt. For example, Antron Corporation, which has a high credit rating, can issue either floating-rate debt at LIBOR + 1% or fixed-rate debt at 10%.[21] Bosworth Industries is less creditworthy, so its cost for floating-rate debt is LIBOR + 1.5% and its fixed-rate cost is 10.4%. Owing to the nature of Antron's operations, its CFO has decided that the firm would be better off with fixed-rate debt; meanwhile, Bosworth's CFO prefers floating-rate debt. Paradoxically, both firms can benefit by issuing the type of debt they do not want and then swapping their payment obligations.

First, each company will issue an identical amount of debt, which is called the **notional principal**. Even though Antron wants fixed-rate debt, it issues floating-rate debt at LIBOR + 1%, and Bosworth issues fixed-rate debt at 10.4%. Next, the two companies enter into an interest rate swap.[22] Assume the debt maturities are 5 years, which means the length of this swap will also be 5 years. By convention, the floating-rate payments of most swaps are based on LIBOR, with the fixed rate adjusted upward or downward to reflect credit risk and the term structure. The riskier the company that will receive the floating-rate payments, the higher the fixed-rate payment it must make. In our example, Antron will be receiving floating-rate payments from Bosworth, and those payments will be set at LIBOR multiplied by the notional principal. Then, payments will be adjusted every 6 months to reflect changes in the LIBOR rate.

The fixed payment that Antron must make to Bosworth is set (that is, "fixed") for the duration of the swap at the time the contract is signed, and it depends primarily on two

[21]LIBOR stands for the London Interbank Offered Rate, the rate charged on interbank dollar loans in the Eurodollar market.

[22]Such transactions are generally arranged by large money center banks, and payments are made to the bank, which in turn pays the interest on the original loans. The bank assumes the credit risk and guarantees the payments should one of the parties default. For its services, the bank receives a percentage of the payments as its fee. In addition, the CME clears swaps similar to these.

The Game of Truth or LIBOR

LIBOR stands for the London Interbank Offered Rate, the rate banks charge one another for loans in the Eurodollar market. LIBOR might possibly be the most important number reported in financial markets because many derivative contracts base payments on LIBOR. Some analysts estimate that there are over $300 trillion of derivatives linked to LIBOR. Because LIBOR is such a widely used rate, you might think that it is reported with the utmost care and accuracy. Wrong!

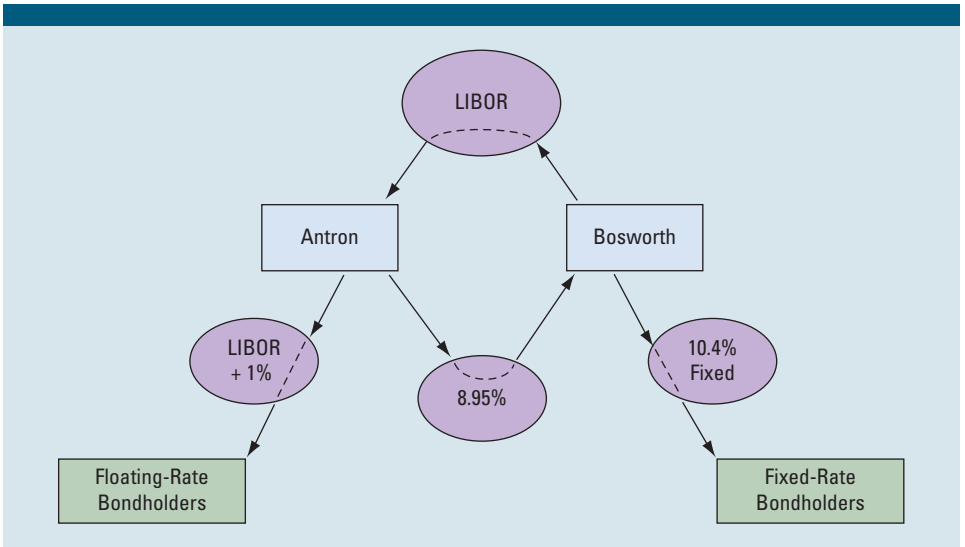
The largest banks in London report to Thomson Reuters the rates they charge one another on loans. Each day Thomson Reuters collects these rates, throws out the highest and lowest percentiles, and uses the middle 50% to calculate the average rate, which it reports to the rest of the world. That part of the process is clear, but how do the banks define the rates that they report? It turns out that some of them just pick a number. On June 27, 2012, Barclays admitted that it had been fined £290 million by U.S. and UK regulators for knowingly reporting untrue rates. Barclays reported low rates at times to disguise how risky other banks viewed Barclays, according to its own e-mails. In addition, some e-mails suggest that Barclays manipulated LIBOR to profit on trades. In the wake of this news, Barclays's CEO and other senior executives were forced to resign.

The Barclays case was just the beginning of a much bigger scandal. In 2013 Deutsche Bank, Société Générale, and Royal Bank of Scotland admitted fixing reported interest rates on the euro version of LIBOR, the EURIBOR, and Citigroup, HSBC, JPMorgan, and Crédit Agricole are being investigated. As of mid-2014, $5.8 billion in fines have been assessed in the combined LIBOR and EURIBOR scandals, with more likely to come.

Note: For more information on the LIBOR and EURIBOR scandal, see **http://topics.nytimes.com/top/reference/timestopics/subjects/l/london_interbank_offered_rate_libor/index.html** and **www.ft.com/intl/indepth/libor-scandal**.

factors: (1) the level of fixed interest rates at the time of the agreement and (2) the relative creditworthiness of the two companies.

In our example, assume interest rates and creditworthiness are such that 8.95% is the appropriate fixed swap rate for Antron, so it will make 8.95% fixed-rate payments to Bosworth. In turn, Bosworth will pay the LIBOR rate to Antron. Table 23-2 shows the net rates paid by each participant, and Figure 23-2 graphs the flows. Note that Antron ends up making fixed payments, which it desires, but because of the swap, the rate paid is 9.95% versus the 10% rate it would have paid had it issued fixed-rate debt directly. At the same time, the swap leaves Bosworth with floating-rate debt, which it wants, but at a rate of LIBOR + 1.45% versus the LIBOR + 1.50% it would have paid on directly issued floating-rate debt. As this example illustrates, swaps can sometimes lower the interest rate paid by each party.



Currency swaps are special types of interest rate swaps. To illustrate, suppose Company A, an American firm, had issued $100 million of dollar-denominated bonds in the

TABLE 23-2
Anatomy of an Interest Rate Swap

Antron's Payments: Borrows Floating, Swaps for Fixed		Bosworth's Payments: Borrows Fixed, Swaps for Floating	
Payment to lender	−(LIBOR + 1%)	Payment to lender	−10.40% fixed
Payment from Bosworth	+LIBOR	Payment from Antron	+8.95% fixed
Payment to Bosworth	−8.95% fixed	Payment to Antron	−LIBOR
Net payment by Antron	−9.95% fixed	Net payment by Bosworth	−(LIBOR + 1.45%)

FIGURE 23-2
The Antron/Bosworth Swap

United States to fund an investment in Germany. Meanwhile, Company G, a German firm, had issued $100 million of euro-denominated bonds in Germany to make an investment in the United States. Company A would earn euros but be required to make payments in dollars, and Company G would be in the opposite situation. Thus, both companies would be exposed to exchange rate risk. However, both companies' risks would be eliminated if they swapped payment obligations.

Originally, swaps were arranged between companies by money center banks, which would match up counterparties. Such matching still occurs, but today most swaps are between companies and banks, with the banks then taking steps to ensure that their own risks are hedged. For example, Citibank might arrange a swap with Company A. Company A would agree to make specified payments in euros to Citibank, while Citibank made dollar payments to Company A. Citibank would charge a fee for setting up the swap, and those charges would reflect the creditworthiness of Company A. To protect itself against exchange rate movements, the bank would hedge its position, either by lining up a European company that needed to make dollar payments or else by using currency futures.[23]

Major changes have occurred over time in the swaps market. First, standardized contracts have been developed for the most common types of swaps, which has had two effects: (1) Standardized contracts lower the time and effort involved in arranging swaps, and this lowers transactions costs. (2) The development of standardized contracts has led to a secondary market for swaps, which has increased the liquidity and efficiency of the swaps market. A number of international banks now make markets in swaps and offer quotes on several standard types. The second major change is due to a provision in

[23]For more information on swaps, see Keith C. Brown and Donald J. Smith, "Default Risk and Innovations in the Design of Interest Rate Swaps," *Financial Management*, Summer 1993, pp. 94–105; Robert Einzig and Bruce Lange, "Swaps at Transamerica: Applications and Analysis," *Journal of Applied Corporate Finance*, Winter 1990, pp. 48–58; John F. Marshall, Vipul K. Bansal, Anthony F. Herbst, and Alan L. the Dodd-Frank Act mandating that certain standardized interest rate swaps be centrally cleared rather than managed by banks. The Chicago Mercantile Group (CME) is one of these clearing houses and as of October, 2014 the notional principal of the swaps outstanding with CME totaled $23 trillion.

Most swaps today involve either interest payments or currencies, but just about anything can be swapped, including equity swaps, credit spread swaps, and commodity swaps.[24]

23-7c Inverse Floaters

A floating-rate note has an interest rate that rises and falls with some interest rate index. For example, if the prime rate were currently 8.5%, then the interest rate on a $100,000 note at prime plus 1% would be 9.5% and the note's rate would move up and down with the prime rate. Because both the cash flows associated with the note and the discount rate used to value it would rise and fall together, the market value of the note would be relatively stable.

With an **inverse floater**, the rate paid on the note moves *counter* to market rates. Thus, if interest rates in the economy rise, the interest rate paid on an inverse floater will fall, reducing its cash interest payments. At the same time, the discount rate used to value the inverse floater's cash flows will rise along with other rates. The combined effect of lower cash flows and a higher discount rate would lead to a large decline in the value of the inverse floater. Thus, inverse floaters are exceptionally vulnerable to increases in interest rates. Of course, if interest rates fall then the value of an inverse floater will soar.

Could an inverse floater be used for hedging purposes? The answer is "yes, perhaps quite effectively." These securities have a magnified effect, so not many are required to hedge a given position. However, because they are so volatile, they could make what is supposed to be a hedged position quite risky.

SELF-TEST

Explain how a company can use Treasury bond futures to hedge against rising interest rates.

What is an interest rate swap? Describe the mechanics of a fixed-rate to floating-rate swap.

A Treasury bond futures contract is selling for 94-16. What is the implied annual yield? **(6.5%)**

Messman Corporation issues fixed-rate debt at a rate of 9.00%. Messman agrees to an interest rate swap in which it pays LIBOR to Moore Inc. and Moore pays 8.75% to Messman. What is Messman's resulting net payment? **(LIBOR + 0.25%)**

23-8 Project Selection Risks

A project is any corporate undertaking that uses corporate assets such as cash, factories, buildings, equipment, IT infrastructure, intellectual property, and people. A successful project creates value by generating a return that is commensurate with the size and risk of the assets invested in the project. Perhaps the most important factor for a company's success is its ability to select value-adding projects and avoid value-destroying projects.

[24]In an equity swap, the cash flow based on an equity index is swapped for some other cash flow. In a commodity swap, the swapped cash flow is based on commodity prices. In a credit swap, the cash flow usually is based on the spread between a risky bond and a U.S. Treasury bond.

23-8a Using Monte Carlo Simulation to Evaluate Project Risk

When evaluating a potential project, a company should assess the project qualitatively and quantitatively using the three-step approach we described in Chapters 10 and 11: (1) Forecast the project's future cash flows. (2) Estimate the value of the cash flows. (3) Analyze the risk of the cash flows.[25] Small projects, such as the replacement of a single machine, require less analysis than large projects, which include major capital expenditures, product line extensions, new products, geographic expansion, acquisitions, and mergers.

For larger projects, it is absolutely vital to conduct a thorough risk analysis, including sensitivity analysis and scenario analysis, as described in Chapter 11. Very large projects require even more risk analysis, including Monte Carlo simulation, which is widely used in enterprise risk management—you can't manage a risk very well if you can't measure it!

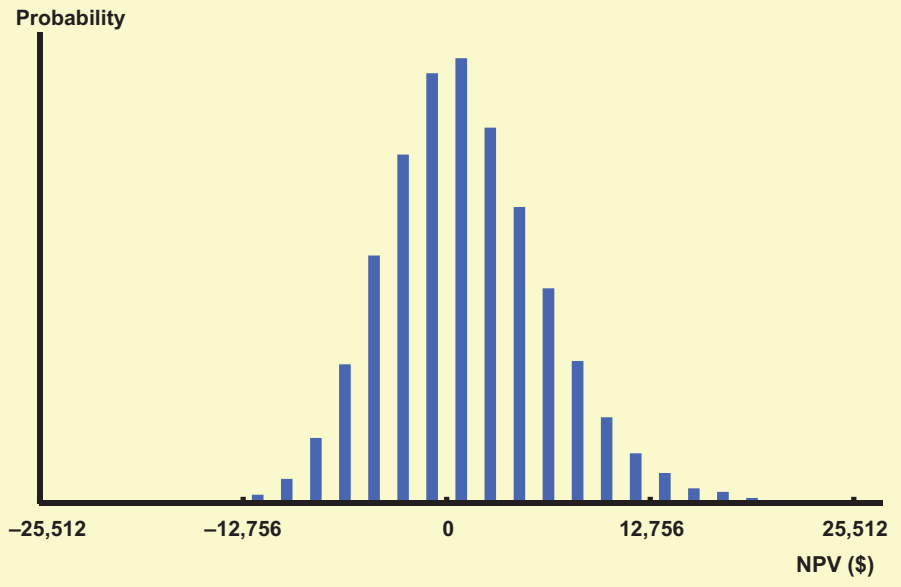
We repeat here some of the results from the simulation analysis in Chapter 11, and we include some new results. Recall that the analysis in Chapter 11 was for the application of a radically new liquid nano-coating technology to a new type of solar water heater module. We projected cash flows for the project, calculated NPV and other evaluation measures, performed a sensitivity analysis, and did a scenario analysis; see Section 11-2 for the basic analysis and Sections 11-5 and 11-6 for the sensitivity and scenario analyses.

We conducted a Monte Carlo simulation analysis in Section 11-7. Recall that in a simulation analysis, a probability distribution is assigned to each input variable—sales in units, the sales price, the variable cost per unit, and so on. The computer begins by picking a random value for each variable from its probability distribution. Those values are then entered into the model, the project's NPV (and any other measures) is calculated, and the NPV is stored in the computer's memory. This is called a trial. After completing the first trial, a second set of input values is selected from the input variables' probability distributions, and a second NPV is calculated. This process is repeated until there are enough observations that the estimated NPV and any other outcome measures are stable.

We replicated the simulation analysis from Chapter 11 with 10,000 iterations; see ***Ch23 Tool Kit.xlsx*** and look in the worksheet ***Simulation***. Figure 23-3 reports the estimated evaluation measures from Chapter 11 and some additional measures.[26] The measures from Chapter 11 for NPV include its average, standard deviation, maximum, minimum, median, and the probability that the NPV will be positive. Based on these measures, the project has a positive expected NPV and will break even about 57% of the time.

In addition to the evaluation measures from Chapter 11, enterprise risk management systems often use another measure called **value at risk (VaR)**. Using the trials from the simulation analysis, the company specifies a threshold, such as the bottom 1% or 5% of outcomes. The basic idea is to measure the value of the project if things go badly. For example, Figure 23-3 shows that there is a 5% chance that the project will lose $6.626 million or more (the values are reported in thousands) and a 1% chance that the project will lose $9.472 million or more.

The VaR measures are helpful, but they don't measure the extent of possible losses if things go badly. A measure that many companies now apply is the **conditional value at risk (CVaR)**; it



[25]Recall from Chapter 10 that cash flow evaluation methods include the net present value (NPV), the internal rate of return (IRR), the modified internal rate of return (MIRR), the profitability index (PI), the payback period, and the discounted payback period.

[26]The values of the measures will be different in this figure than in Figure 11-7 since these results are from another run of 10,000 trials for the simulation. Each new run of the simulation will give slightly different results.

is also called the **expected shortfall**, the expected tail loss (ETL), and the average value at risk (AVaR). The CVaR measures the average NPV of all outcomes below the threshold—it is the average NPV conditional upon the NPV being less than the threshold value.[27] For example, the CVaR for the 1% threshold is –$10.950 million, which means that if the worst 1% of outcomes occur, the expected loss is $10.950 million. Notice that the VaR calculation is not affected by the size of the losses below the threshold—it just tells you size of the loss *at* the threshold percentile. In contrast, the CVaR takes into account the size of the losses *below* the threshold—it shows the expected loss if things go badly.

Many companies now are applying simulation when they analyze mergers and acquisition. In addition to the quantitative output from a simulation analysis, the process of identifying sources of risk can help companies avoid costly mistakes.

[27]This definition is correct when applying CVaR to the outcomes from a Monte Carlo simulation because there is an equal probability of each outcome. It is a little more complicated to calculate CVaR from a given probability distribution than it is from the outcomes of a simulation.

23-8b Using Monte Carlo Simulation to Evaluate Financing Risks

Companies use simulation for purposes other than project analysis. For example, the Danish maker of the popular plastic building-brick toys, the LEGO Group, also uses simulation in its budgeting process to show the possible outcomes. CFO Hans Læssøe reports that simulation analysis revealed that sales volatility has a much bigger impact than top managers previously understood.[28]

Simulation also is helpful when a company prepares a cash budget such as the one we described in Chapter 16. Rather than just showing the expected short-term financing requirements, simulation can show the probabilities of a larger financing requirement, allowing companies to plan for previously unexpected credit needs.

23-8c Using Monte Carlo Simulation to Evaluate Portfolio Risks

Many companies are exposed to portfolio risk, which is the risk that a portfolio of financial assets will decrease in value. For example, many companies offer pension plans to their employees. Defined benefit plans have a portfolio of stocks, bonds, and other financial assets that is used to support promised pension benefits to its employees. Such companies are exposed to significant portfolio risk—if the value of the pension assets portfolio drops too much relative to the value of the promised pension benefits, then the company will have to use its other resources to make additional contributions to the plan.

Most financial institutions are also exposed to portfolio risk because they own financial assets and have financial liabilities. Simulation is a widely used tool for measuring a bank's portfolio risk. In fact, the Basel II and III accords require banks to report their VaR and the Basel Committee is presently (2015) considering requiring banks to also report the expected shortfall (the CVaR).

When the trading and risk management groups at financial institutions use VaR (or CVaR), they usually measure it over a very short time horizon because they want to know how much they might lose overnight or within a couple of days.

SELF-TEST

What is Monte Carlo simulation?

What is value at risk, VaR? What is conditional value at risk, CVaR?

23-9 Managing Credit Risks

Nonfinancial companies are exposed to risk if they extend credit to their customers, and financial institutions are exposed to credit risk when they lend to their customers. Following are some key concepts in the management of credit risk.

23-9a Managing Credit Risk at Nonfinancial Companies

As we described in Chapter 16, when a company sells a product to a customer but does not require immediate payment, an account receivable is created. There are three primary tools that companies use to manage this credit risk.

[28]See the paper by Mark Frigo and Hans Læssøe cited in footnote 10.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

First, a company evaluates its customers before extending credit. The company can do its own evaluation or purchase an evaluation from a third party. If the customer is an individual, credit evaluations are available from several companies, including as Equifax, Experian, and TransUnion. Each of these companies provides a numerical score, with the FICO score being the most widely used. The score ranges from 300 to 850, with lower scores indicating that the customer is more likely to default.

When the customer is another company, the evaluation is conducted using many of the same ratios and analyses we described in Chapter 3. In addition, some companies create their own credit scoring models based on past experience or statistical models (such as multiple discriminant analysis).

A company can mitigate its credit risk by selling its accounts receivable to a third party in a process called factoring. Of course, the price a company receives from selling its receivables depends on the receivables' risk, with riskier receivables purchased for much less than their nominal value. A company can also buy insurance for some or all of its receivables. Many companies, including the LEGO Group, use simulation to estimate the risk of their receivables so that they can better negotiate with insurers.

23-9b Managing Credit Risk at Financial Institutions

WWW

See the Markit Group Limited's Web site for updates on CDS data. Free registration allows access to a variety of current data, including indexes: **www.markit.com/en**.

In addition to the same techniques used at nonfinancial corporations (credit scoring models and simulation), many financial institutions use credit default swaps (CDS). Even though CDS are called swaps, they are like insurance. For example, an investor (which might be a financial institution) might purchase a CDS by making an annual payment to a counterparty to insure a particular bond or other security against default; if the bond defaults, the counterparty pays the purchaser the amount of the defaulted bond that was insured.

The CDS "price" is quoted in basis points and is called the CDS spread. For example, the spread on Unitymedia KabelBW GmbH, a German cable operator, was about 271 basis points in May 2014. An easy way to interpret the reported basis point spread is that it would be the annual fee in dollars (or euros) to protect $10,000 (or euros) of the bond. Therefore, it would cost €271 per year to insure €10,000 of Unitymedia's bonds.

To protect €10 million of Unitymedia's debt, a buyer would pay €271,000 = 0.0271(€10 million) per year. In contrast, the spread on the automobile manufacturer BMW's bonds was only 42 basis points, so insuring €10 million of BMW's debt would cost only €42,000 per year. If the investors owned the bonds, then the purchase of the CDS would reduce the investor's risk.

There is an active secondary market for CDS, and it is not necessary to own the underlying security. In fact, most participants in the CDS market don't own the underlying securities. For example, a speculator might purchase a CDS on Unitymedia for 271 basis points but only purchase coverage for 1 month, which would be a payment of €22,583 = €271,000/12. Now suppose the Eurozone's problems immediately worsened and drove Unitymedia's CDS spread up to 300 basis points. The investor could liquidate the position by selling 1-month credit protection for €25,000 = €300,000/12 and use the previously purchased CDS to offset the newly sold CDS. The investor's profit would be €2,417.

In addition to CDS for individual securities, there are CDS for indices. For example, the CDX.NA.IG is an index of 125 CDS for North American investment-grade debt. The index's movements are positively correlated with the overall level of default for many commercial loans—the index goes up when defaults increase. Therefore, a U.S. bank can

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

protect itself from increasing default rates in its loan portfolio by taking a short position in the CDX.NA.IG. If defaults increase, then the index goes up, which means a short investor can profit by selling the now higher priced index at the lower price specified in the original short position. This is a situation in which the CDS help reduce a financial institution's risk—when defaults increase, the institution loses money on it loans but makes money on the index. Of course, if the index falls, then the bank loses on the short position but wins on its own loan portfolio because there are fewer defaults.

Recall from the opening vignette that JPMorgan took *long* positions in a particular series of the CDX.NA.IG, which certainly wasn't to hedge its loan portfolios. JPMorgan explained that it was to hedge other derivatives that were hedging its loan portfolio, which sounds very complicated—no wonder it didn't work!

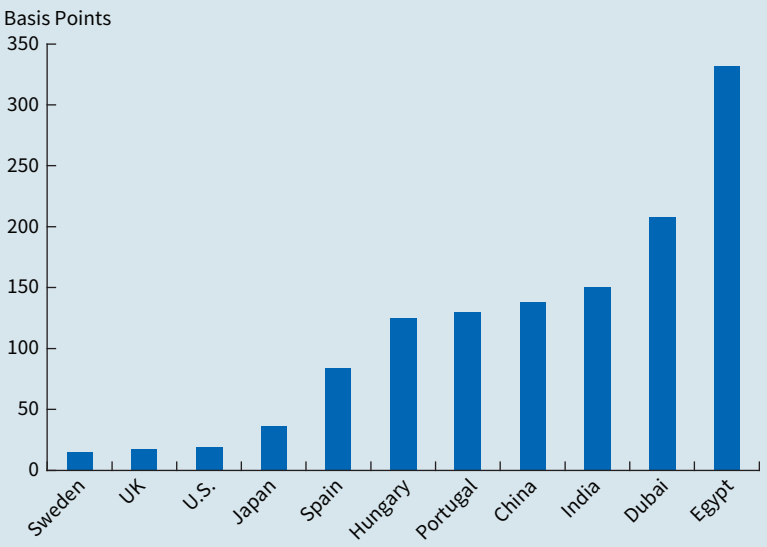
When banks and other major financial institutions take positions in swaps and CDS, they are themselves exposed to various risks, especially if their counterparties cannot meet their obligations. Furthermore, swaps are off–balance sheet transactions, making it impossible to tell just how large the swap market is or who has what obligation. The Bank of International Settlements estimates that as of the end of 2014 the notional value of all CDS was $16 trillion. As we write this in the summer of 2015, the SEC and the Commodity Futures Trading Commission (CFTC) continue implementation of provisions in Title VII of the 2010 Dodd-Frank Act to improve transparency in the swaps markets. Standardized interest-rate and credit-default swaps must now be centrally cleared and the market is working to develop new products that provide the same benefits as these swaps, but with lower counterparty risk.[29]

Credit default swaps are traded on government debt as well as corporate debt. Before 2008, a CDS on a 5-year U.S. Treasury bond was trading at less than 7 basis points, which would be a $7 annual fee to protect $10,000 of the bond. The CDS price increased to almost 100 basis points in 2009, and is currently (May 2015) trading around 20 basis points. Figure 23-4 shows the prices for the U.S. and selected European countries, some that have adopted the euro (Germany, France, Italy, Spain, and Portugal) and some that have not. The extremely high prices for Eurozone debt indicate the problems facing these countries.

SELF-TEST

Describe some ways to manage credit risk at a nonfinancial company.

What are credit default swaps?



23-10 Risk and Human Safety

Risk management decisions, like all corporate decisions, should begin with a cost–benefit analysis for each feasible alternative. For example, suppose it would cost $50,000 per year to conduct a comprehensive fire safety training program for all personnel in a high-risk plant. Presumably, this program would reduce the expected value of future fire losses. An alternative to the training program would be to place $50,000 annually in a reserve fund set aside to cover future fire losses. Both alternatives involve expected cash flows, and from an economic standpoint the choice should be made on the basis of the lowest present value of future costs.

Credit Default Swap Spreads for Sovereign Debt (April 13, 2015)

Source: CNBC News, **www.cnbc.com/id/38451750**.

However, suppose a fire occurs and a life is lost. In situations involving safety and health, the trade-off between expected profits and expected losses is not sufficient for making sound decisions. Companies must always consider the impact their decisions have on the safety of their employees and customers. Ignoring safety and health is an ethical mistake, but it also is a business mistake because many companies have been forced out of business or suffered debilitating losses when they produced unsafe products.

SELF-TEST

Describe a situation in risk management that involves ethical as well as financial issues.

SUMMARY

The key concepts in enterprise risk management are listed here.

- **Enterprise risk management (ERM)** includes risk identification, risk assessment, and risk responses.
- A **derivative** is a security whose value is determined by the market price or interest rate of some other security.
- Risk management allows corporations: (1) to increase their use of debt, (2) to maintain their capital budget over time, (3) to avoid costs associated with financial distress, (4) to utilize their comparative advantages in hedging relative to the hedging ability of individual investors, (5) to reduce both the risks and costs of borrowing by using **swaps**, and (6) to reduce the higher taxes that result from fluctuating earnings. Managers may also want to stabilize earnings in order to boost their own compensation.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- Risk responses include: (1) avoiding the activity, (2) reducing the probability of occurrence of an adverse event, (3) reducing the magnitude of the loss associated with an adverse event, (4) transferring the risk to an insurance company, (5) transferring the function that produces the risk to a third party, and (6) sharing the risk by purchasing a derivative contract.
- Major categories of risk include: (1) strategy and reputation, (2) control and compliance, (3) hazards, (4) human resources, (5) operation, (6) technology, and (7) financial management.
- Types of financial risk include: (1) foreign exchange risk, (2) commodity price risk, (3) interest rate risk, (4) project selection risk, (5) liquidity risk, (6) customer credit risk, and (7) portfolio risk.
- A **hedge** is a transaction that lowers risk. A **natural hedge** is a transaction between two **counterparties** whose risks are mirror images of each other.
- A **futures contract** is a standardized contract that is traded on an exchange and is marked-to-market daily, although physical delivery of the underlying asset usually does not occur.
- Under a **forward contract**, one party agrees to buy a commodity at a specific price and a specific future date and the other party agrees to make the sale; delivery does occur.
- A **swap** is an exchange of cash payment obligations. Swaps occur because the parties involved prefer the other's payment stream.
- **Financial futures** permit firms to create hedge positions to protect themselves against fluctuating interest rates, stock prices, and exchange rates.
- **Commodity futures** can be used to hedge against input price increases.
- **Long hedges** involve buying futures contracts to guard against price increases.
- **Short hedges** involve selling futures contracts to guard against price declines.
- **Symmetric hedges** protect against price increases and price decreases. Futures contracts are frequently used for symmetric hedges.
- **Asymmetric hedges** protect against price movements in one direction more than movements in another. Options are frequently used for asymmetric hedges.
- A **perfect hedge** occurs when the gain or loss on the hedged transaction exactly offsets the loss or gain on the unhedged position.

QUESTIONS

(23-1) Define each of the following terms:

a. Derivatives
b. Enterprise risk management
c. Financial futures; forward contract
d. Hedging; natural hedge; long hedge; short hedge; perfect hedge; symmetric hedge; asymmetric hedge
e. Swap; structured note
f. Commodity futures

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(23-2) Give two reasons why stockholders might be indifferent between owning the stock of a firm with volatile cash flows and that of a firm with stable cash flows.

(23-3) List six reasons why risk management might increase the value of a firm.

(23-4) Discuss some of the techniques available to reduce risk exposures.

(23-5) Explain how the futures markets can be used to reduce interest rate risk and input price risk.

(23-6) How can swaps be used to reduce the risks associated with debt contracts?

SELF-TEST PROBLEM — Solution Shown in Appendix A

(ST-1) Hedging It is now March, and the current cost of debt for Wansley Construction is 12%. Wansley plans to issue $5 million in 20-year bonds (with coupons paid semiannually) in September, but it's afraid that rates will climb even higher before then. The following data are available:

Futures Prices: Treasury Bonds—$100,000; Pts. 32nds of 100%

Delivery Month (1)	Open (2)	High (3)	Low (4)	Settle (5)	Change (6)
Mar	96'28	97'13	97'22	98'05	+7
June	98'03	98'03	97'13	97'25	+8
Sept	97'03	97'17	97'03	97'13	+8

a. What is the implied interest rate on the September contract?
b. Construct a hedge for Wansley.
c. Assume all interest rates rise by 1 percentage point. What is the dollar value of Wansley's increased cost of issuing debt? What is Wansley's gain from the futures contract?

PROBLEMS — Answers Are in Appendix B

EASY PROBLEMS 1–2

(23-1) Swaps Zhao Automotive issues fixed-rate debt at a rate of 7.00%. Zhao agrees to an interest rate swap in which it pays LIBOR to Lee Financial and Lee pays 6.8% to Zhao. What is Zhao's resulting net payment?

(23-2) Futures A Treasury bond futures contract has a settlement price of 89'08. What is the implied annual yield?

INTERMEDIATE PROBLEMS 3–4

(23-3) Futures What is the implied interest rate on a Treasury bond ($100,000) futures contract that settled at 100'16? If interest rates increased by 1%, what would be the contract's new value?

(23-4) Swaps Carter Enterprises can issue floating-rate debt at LIBOR + 2% or fixed-rate debt at 10%. Brence Manufacturing can issue floating-rate debt at LIBOR + 3.1% or fixed-rate debt at 11%.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Suppose Carter issues floating-rate debt and Brence issues fixed-rate debt. They are considering a swap in which Carter makes a fixed-rate payment of 7.95% to Brence and Brence makes a payment of LIBOR to Carter. What are the net payments of Carter and Brence if they engage in the swap? Would Carter be better off if it issued fixed-rate debt or if it issued floating-rate debt and engaged in the swap? Would Brence be better off if it issued floating-rate debt or if it issued fixed-rate debt and engaged in the swap? Explain your answers.

CHALLENGING PROBLEM 5

(23-5) Hedging

The Zinn Company plans to issue $10,000,000 of 20-year bonds in June to help finance a new research and development laboratory. The bonds will pay interest semiannually. It is now November, and the current cost of debt to the high-risk biotech company is 11%. However, the firm's financial manager is concerned that interest rates will climb even higher in coming months. The following data are available:

Futures Prices: Treasury Bonds—$100,000; Pts. 32nds of 100%

Delivery Month (1)	Open (2)	High (3)	Low (4)	Settle (5)	Change (6)	Open Interest (7)
Dec	94'28	95'13	94'22	95'05	+0'07	591,944
Mar	96'03	96'03	95'13	95'25	+0'08	120,353
June	95'03	95'17	95'03	95'17	+0'08	13,597

a. Use the given data to create a hedge against rising interest rates.
b. Assume that interest rates in general increase by 200 basis points. How well did your hedge perform?
c. What is a perfect hedge? Are any real-world hedges perfect? Explain.

SPREADSHEET PROBLEM

(23-6) Build a Model: Hedging

resource

Start with the partial model in the file ***Ch23 P06 Build a Model.xlsx*** on the textbook's Web site. Use the following information and data.

F. Pierce Products Inc. is financing a new manufacturing facility with the issue in March of $20,000,000 of 20-year bonds with semiannual interest payments. It is now October, and if Pierce were to issue the bonds now, the yield would be 10% because of Pierce's high risk. Pierce's CFO is concerned that interest rates will climb even higher in coming months and is considering hedging the bond issue. The following data are available:

Futures Prices: Treasury Bonds—$100,000; Pts. 32nds of 100%

Delivery Month (1)	Open (2)	High (3)	Low (4)	Settle (5)	Change (6)	Open Interest (7)
Dec	93'28	94'13	93'22	94'05	+0'06	723,946
Mar	95'03	95'03	94'13	94'25	+0'07	97,254

a. Create a hedge with the futures contract for Pierce's planned March debt offering of $20 million using the March Treasury bond futures contract. What is the implied yield on the bond underlying the futures contract?

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

b. Suppose that interest rates fall by 300 basis points. What are the dollar savings from issuing the debt at the new interest rate? What is the dollar change in value of the futures position? What is the total dollar value change of the hedged position?
c. Create a graph showing the effectiveness of the hedge if the change in interest rates, in basis points, is −300, −200, −100, 0, 100, 200, or 300. Show the dollar cost (or savings) from issuing the debt at the new interest rates, the dollar change in value of the futures position, and the total dollar value change.

MINI CASE

Assume you have just been hired as a financial analyst by Tennessee Sunshine Inc. (TS), a mid-sized Tennessee company that specializes in creating exotic sauces from imported fruits and vegetables. The firm's CEO, Bill Stooksbury, recently returned from an industry corporate executive conference in San Francisco, and one of the sessions he attended was on the pressing need for companies to institute enterprise risk management programs. Because no one at Tennessee Sunshine is familiar with the basics of enterprise risk management, Stooksbury has asked you to prepare a brief report that the firm's executives could use to gain at least a cursory understanding of the topics.

To begin, you gathered some outside materials on derivatives and risk management and used these materials to draft a list of pertinent questions that need to be answered. In fact, one possible approach to the paper is to use a question-and-answer format. Now that the questions have been drafted, you have to develop the answers.

a. Why might stockholders be indifferent to whether or not a firm reduces the volatility of its cash flows?
b. What are six reasons risk management might increase the value of a corporation?
c. What is COSO? How does COSO define enterprise risk management?
d. Describe the eight components of the COSO ERM framework.
e. Describe some of the risks events within the following major categories of risk: (1) strategy and reputation, (2) control and compliance, (3) hazards, (4) human resources, (5) operations, (6) technology, and (7) financial management.
f. What are some actions that companies can take to minimize or reduce risk exposures?
g. What are forward contracts? How can they be used to manage foreign exchange risk?
h. Describe how commodity futures markets can be used to reduce input price risk.
i. It is January, and Tennessee Sunshine is considering issuing $5 million in bonds in June to raise capital for an expansion. Currently, the firm can issue 20-year bonds with a 7% coupon (with interest paid semiannually), but interest rates are on the rise and Stooksbury is concerned that long-term interest rates might rise by as much as 1% before June. You looked online and found that June T-bond futures are trading at 111'25. What are the risks of not hedging, and how might TS hedge this exposure? In your analysis, consider what would happen if interest rates all increased by 1%.
j. What is a swap? Suppose two firms have different credit ratings. Firm Hi can borrow fixed at 11% and floating at LIBOR + 1%. Firm Lo can borrow fixed at 11.4% and floating at LIBOR + 1.5%. Describe a floating versus fixed interest rate swap between firms Hi and Lo in which Lo also makes a "side payment" of 45 basis points to Firm L.

CHAPTER 24

Bankruptcy, Reorganization, and Liquidation

Lehman Brothers, Washington Mutual, Chrysler, and General Motors all filed for bankruptcy protection during the Great Recession. What did these four filings have in common with Australia? At the time of filings, the companies' assets totaled over $1.1 trillion dollars, which is about the same size as Australia's annual gross domestic product.

With $691 billion in assets, Lehman Brothers holds the record for the largest bankruptcy filing in history. Its operations and assets have been liquidated and sold piecemeal to other companies, including Barclays. Washington Mutual (WaMu) once was the largest S&L in the United States, with total assets of $328 billion in September 2008. But when it sustained enormous losses related to sub-prime mortgages, WaMu was placed into the Federal Deposit Insurance Corporation's (FDIC) receivership. The FDIC quickly sold WaMu's banking operations to JPMorgan Chase.

Chrysler filed for bankruptcy on April 30, 2009, and emerged from bankruptcy 40 days later on June 10, 2009. As part of the deal, Chrysler's new owners include its employees/retirees (through pension and health care funds), Fiat, and the U.S. government. Cerberus Capital, a private equity fund that was Chrysler's owner prior to the bankruptcy, lost its entire equity stake, and Chrysler's pre-bankruptcy debt-holders are receiving pennies on the dollar.

When GM filed for bankruptcy on June 1, it became the largest manufacturer in U.S. history to fail. When GM emerged from bankruptcy 40 days later, the U.S. government owned 60.8% of the equity in the "new" GM, with the remaining equity owned by the Canadian government (11.7%), the UAW employee health care trust (17.5%), and former bondholders (10%). Notice that nothing was left for former stockholders.

As you read this chapter, think about the decisions that were made in the bank-ruptcy processes of these four companies.

The textbook's Web site contains an Excel *file that will guide you through the chapter's calculations. The file for this chapter is* ***Ch24 Tool Kit.xlsx,*** *and we encourage you to open the file and follow along as you read the chapter.*

Thus far, we have dealt with issues faced by growing, successful enterprises. However, many firms encounter financial difficulties, and some—including such big names as General Motors, Chrysler, Delta Air Lines, and Lehman Brothers—are forced into bankruptcy. When a firm encounters financial distress, its managers must try to ward off a total collapse and thereby minimize losses. The ability to hang on during rough times often means the difference between forced liquidation versus rehabilitation and eventual success. An understanding of bankruptcy is also critical to the executives of healthy firms, because they must know the best actions to take when their customers or suppliers face the threat of bankruptcy.

24-1 Financial Distress and Its Consequences

We begin with some background on financial distress and its consequences.[1]

24-1a Causes of Business Failure

A company's intrinsic value is the present value of its expected future free cash flows. Many factors can cause this value to decline. These include general economic conditions, industry trends, and company-specific problems such as shifting consumer tastes, obsolete technology, and changing demographics in existing retail locations. Financial factors, such as too much debt and unexpected increases in interest rates, can also cause business failures. The importance of the different factors varies over time, and most business failures occur because a number of factors combine to make the business unsustainable. Further, case studies show that financial difficulties are usually the result of a series of errors, misjudgments, and interrelated weaknesses that can be attributed directly or indirectly to management. In a few cases, such as Enron and MF Global Holdings, fraud leads to bankruptcy.

resource

As you might guess, signs of potential financial distress are generally evident in a ratio analysis long before the firm actually fails, and researchers use ratio analysis to estimate the probability that a given firm will go bankrupt. Financial analysts constantly are seeking ways to assess a firm's likelihood of going bankrupt. We discuss one method, multiple discriminant analysis (MDA), in ***Web Extension 24A***.

24-1b The Business Failure Record

Although bankruptcy is more frequent among smaller firms, it is clear from Table 24-1 that large firms are not immune. This was especially true in the Great Recession: Six of the largest bankruptcies occurred in 2008 and 2009.

Bankruptcy obviously is painful for a company's shareholders, but it also can be harmful to the economy if the company is very large or is in a critical sector. For example, the failure of Lehman Brothers in September 2008 sparked a global run on financial institutions that froze credit markets and contributed to the ensuing global recession. It is not clear whether the damage to the world economy could have been mitigated if the government had intervened to prevent Lehman's failure, but the government subsequently decided not to take chances with many other troubled financial institutions. For example, the government helped arrange the 2008 acquisition of Wachovia by Wells Fargo, the 2008 acquisition of Bear Stearns by JPMorgan Chase, and the 2009 acquisition of Merrill

[1]Much of the current academic work in the area of financial distress and bankruptcy is based on writings by Edward I. Altman. See Edward I. Altman and Edith Hotchkiss, *Corporate Financial Distress and Bankruptcy: Predict and Avoid Bankruptcy, Analyze and Invest in Distressed Debt* (Hoboken, NJ: Wiley, 2006).

Lynch by Bank of America (despite Bank of America's misgivings). In addition, the government provided billions of dollars of capital to many major financial institutions in 2008, including AIG. In each of these cases, the government decided that a complete failure of these institutions might cause the entire financial system to collapse.

In other cases, the government has decided that a company was too important to the nonfinancial side of the economy to be allowed to go through liquidation. For example, in 2008 and 2009 the government provided billions of dollars of financing to General Motors and Chrysler. Even though these companies subsequently went through bankruptcy proceedings in 2009, they avoided liquidation, still have a significant number of employees, and remain major players in the automobile industry. In past years, the government also has intervened to support troubled firms in other critical sectors, such as Lockheed and Douglas Aircraft in the defense industry.

SELF-TEST

What are the major causes of business failure?

Do business failures occur evenly over time?

Which size of firm, large or small, is most prone to business failure? Why?

24-2 Issues Facing a Firm in Financial Distress

Financial distress begins when a firm is unable to meet scheduled payments or when cash flow projections indicate that it will soon be unable to do so. As the situation develops, five central issues arise.

1. Is the firm's inability to meet scheduled debt payments a temporary cash flow problem, or is it a permanent problem caused by asset values having fallen below debt obligations?
2. If the problem is temporary, then an agreement with creditors that gives the firm time to recover and to satisfy everyone may be worked out. However, if basic long-run asset values have truly declined, then economic losses have occurred. In this event, who should bear the losses, and who should get whatever value remains?

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

3. Is the company "worth more dead than alive"? That is, would the business be more valuable if it were liquidated and sold off in pieces or if it were maintained and continued in operation?
4. Should the firm file for protection under Chapter 11 of the Bankruptcy Act, or should it try to use informal procedures? (Both reorganization and liquidation can be accomplished either informally or under the direction of a bankruptcy court.)
5. Who should control the firm while it is being liquidated or rehabilitated? Should the existing management be left in charge, or should a trustee be placed in charge of operations?

In the remainder of the chapter, we discuss these issues in turn.

SELF-TEST

What five major issues must be addressed when a firm faces financial distress?

24-3 Settlements without Going through Formal Bankruptcy

When a firm experiences financial distress, its managers and creditors must decide whether the problem is temporary and the firm is financially viable or whether a permanent problem exists that endangers the firm's life. Then the parties must decide whether to try to solve the problem informally or under the direction of a bankruptcy court. Because of costs associated with formal bankruptcy—including the disruptions that occur when a firm's customers, suppliers, and employees learn that it has filed under the Bankruptcy Act—it is preferable to reorganize (or liquidate) outside of formal bankruptcy. We first discuss informal settlement procedures and then the procedures under a formal bankruptcy.

24-3a Informal Reorganization

In the case of an economically sound company whose financial difficulties appear to be temporary, creditors are generally willing to work with the company to help it recover and reestablish itself on a sound financial basis. Such voluntary plans, commonly called **workouts**, usually require a **restructuring** of the firm's debt, because current cash flows are insufficient to service the existing debt. Restructuring typically involves extension and/or composition. In an **extension**, creditors postpone the dates of required interest or principal payments, or both. In a **composition**, creditors voluntarily reduce their fixed claims on the debtor by accepting a lower principal amount, by reducing the interest rate on the debt, by taking equity in exchange for debt, or by some combination of these changes.

An **informal debt restructuring** begins with a meeting between the failing firm's managers and creditors. The creditors appoint a committee consisting of four or five of the largest creditors plus one or two of the smaller ones. This meeting is often arranged and conducted by an **adjustment bureau** associated with and run by a local credit managers' association.[2] The first step is for management to draw up a list of creditors that shows the amounts of debt owed. There are typically different classes of debt, ranging

[2]There is a nationwide group called the National Association of Credit Management, which consists of bankers and industrial companies' credit managers. This group sponsors research on credit policy and problems, conducts seminars on credit management, and operates local chapters in cities throughout the nation. These local chapters frequently operate adjustment bureaus.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

from first-mortgage holders to unsecured creditors. Next, the company develops information showing the value of the firm under different scenarios. Typically, one scenario is going out of business, selling off the assets, and then distributing the proceeds to the various creditors in accordance with the priority of their claims, with any surplus going to the common stockholders. The company may hire an appraiser to get an appraisal of the value of the firm's property to use as a basis for this scenario. Other scenarios include continued operations, frequently with some improvements in capital equipment, marketing, and perhaps some management changes.

This information is then shared with the firm's bankers and other creditors. Frequently, the firm's debts exceed its liquidating value, and the legal fees and other costs associated with a formal liquidation under federal bankruptcy procedures will materially lower the net proceeds available to creditors. Furthermore, it generally takes at least a year (and often several years) to resolve matters in a formal proceeding, so the present value of the eventual proceeds will be lower still. This information, when presented in a credible manner, often convinces creditors they would be better off accepting something less than the full amount of their claims rather than holding out for the full face amount. If management and the major creditors agree that the problems can probably be resolved, then a more formal plan is drafted and presented to all the creditors, along with the reasons creditors should be willing to compromise on their claims.

In developing the reorganization plan, creditors prefer an extension because it promises eventual payment in full. In some cases, creditors may agree not only to postpone the date of payment but also to subordinate existing claims to vendors who are willing to extend new credit during the workout period. Similarly, creditors may agree to accept a lower interest rate on loans during the extension, perhaps in exchange for a pledge of collateral. Because of the sacrifices involved, the creditors must have faith that the debtor firm will be able to solve its problems.

In a composition, creditors agree to reduce their claims. Typically, creditors receive cash and/or new securities that have a combined market value that is less than the amounts owed them. The cash and securities, which might have a value of only 10% of the original claim, are taken as full settlement of the original debt. Bargaining will take place between the debtor and the creditors over the savings that result from avoiding the costs of legal bankruptcy: administrative costs, legal fees, investigative costs, and so on. In addition to escaping such costs, the debtor gains because the stigma of bankruptcy may be avoided. As a result, the debtor may be induced to part with most of the savings from avoiding formal bankruptcy.

Often, the bargaining process will result in a restructuring that involves both extension and composition. For example, the settlement may provide for a cash payment of 25% of the debt immediately plus a new note promising six future installments of 10% each, for a total payment of 85%.

Voluntary settlements are both informal and simple; they are also relatively inexpensive, because legal and administrative expenses are held to a minimum. Thus, voluntary procedures generally result in the largest return to creditors. Although creditors do not obtain immediate payment and may even have to accept less than is owed them, they generally recover more money, and sooner, than if the firm were to file for bankruptcy.

In recent years, the fact that restructurings can sometimes help creditors avoid showing a loss has motivated some creditors, especially banks and insurance companies, to agree to voluntary restructurings. Thus, a bank "in trouble" with its regulators over weak capital ratios may agree to extend loans that are used to pay the interest on earlier loans—in order to keep the bank from having to write down the value of those earlier loans. This particular type of restructuring depends on: (1) the willingness of the regulators to go along with the process, and (2) whether the bank is likely to recover more by restructuring the debt than by forcing the borrower into bankruptcy immediately.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

We should point out that informal voluntary settlements are not reserved for small firms. International Harvester (now Navistar International) avoided formal bankruptcy proceedings by getting its creditors to agree to restructure more than $3.5 billion of debt. Likewise, Chrysler's creditors accepted both an extension and a composition to help it through its bad years in the late 1970s before it merged with Daimler-Benz. The biggest problem with informal reorganizations is getting all the parties to agree to the voluntary plan. This problem, called the *holdout* problem, is discussed in a later section.

24-3b Informal Liquidation

When it is obvious that a firm is more valuable dead than alive, informal procedures can also be used to sell the firm's asset in a **liquidation**. **Assignment** is an informal procedure for liquidating a firm, and it usually yields creditors a larger amount than they would get in a formal bankruptcy liquidation. However, assignments are feasible only if the firm is small and its affairs are not too complex. An assignment calls for title to the debtor's assets to be transferred to a third party, known as an **assignee** or trustee. The assignee is instructed to liquidate the assets through a private sale or public auction and then to distribute the proceeds among the creditors on a pro rata basis. The assignment does not automatically discharge the debtor's obligations. However, the debtor may have the assignee write the requisite legal language on the check to each creditor so that endorsement of the check constitutes acknowledgment of full settlement of the claim.

Assignment has some advantages over liquidation in federal bankruptcy courts in terms of time, legal formality, and expense. The assignee has more flexibility in disposing of property than does a federal bankruptcy trustee, so action can be taken sooner, before inventory becomes obsolete or machinery rusts. Also, because the assignee is often familiar with the debtor's business, better results may be achieved. However, an assignment does not automatically result in a full and legal discharge of all the debtor's liabilities, nor does it protect the creditors against fraud. Both of these problems can be reduced by formal liquidation in bankruptcy, which we discuss in a later section.

SELF-TEST

Define the following terms: (1) restructuring, (2) extension, (3) composition, (4) assignment, and (5) assignee (trustee).

What are the advantages of liquidation by assignment versus a formal bankruptcy liquidation?

24-4 Federal Bankruptcy Law

U.S. bankruptcy laws were first enacted in 1898. They were modified substantially in 1938 and again in 1978, and some fine-tuning was done in 1986. In 2005, Congress further modified the bankruptcy code, speeding up bankruptcy proceedings for companies and making it more difficult for consumers to take advantage of provisions that can wipe out certain debts. The primary purpose of the bankruptcy law is to prevent individual creditors from forcing the liquidation of firms that are worth more as ongoing concerns, and thus causing harm to other stakeholders.

Currently, our bankruptcy law consists of eight odd-numbered chapters, plus one even-numbered chapter. (The old even-numbered chapters were deleted when the act was revised in 1978.) Chapters 1, 3, and 5 contain general provisions applicable to the other chapters. **Chapter 11**, which deals with **reorganization in bankruptcy**, is the most important section from a financial management viewpoint. **Chapter 7** details the procedures to be followed when liquidating a firm; generally, Chapter 7 does not come into play

unless it has been determined that reorganization under Chapter 11 is not feasible. Chapter 9 deals with financially distressed municipalities; Chapter 12 covers special procedures for family-owned farms; Chapter 13 covers the adjustment of debts for "individuals with regular income"; and Chapter 15 sets up a system of trustees who help administer proceedings under the act.

A firm is officially bankrupt when it files for bankruptcy with a federal court. When you read that a company such as General Motors has "filed for court protection under Chapter 11," this means the company is attempting to reorganize under the supervision of a bankruptcy court. Formal bankruptcy proceedings are designed to protect both the firm and its creditors. On the one hand, if the problem is temporary insolvency, then the firm may use bankruptcy proceedings to gain time to solve its cash flow problems without asset seizure by its creditors. On the other hand, if the firm is truly bankrupt in the sense that liabilities exceed assets, then creditors can use bankruptcy procedures to stop the firm's managers from continuing to operate, lose more money, and thus deplete assets that should go to creditors.

Bankruptcy law is flexible in that it provides scope for negotiations between a company, its creditors, its labor force, and its stockholders. A case is opened by filing a **petition** with one of the 291 bankruptcy courts serving 90 judicial districts. The petition may be either **voluntary** or **involuntary**; that is, it may be filed either by the firm's management or by its creditors. After a filing, a committee of unsecured creditors is then appointed by the Office of the U.S. Trustee to negotiate with management for a reorganization, which may include the restructuring of debt. Under Chapter 11, a **trustee** will be appointed to take over the company if the court deems current management incompetent or if fraud is suspected. Normally, though, the existing management retains control. If no fair and feasible reorganization can be worked out, the bankruptcy judge will order that the firm be liquidated under procedures spelled out in Chapter 7 of the Bankruptcy Act, in which case a trustee will always be appointed.[3]

SELF-TEST

Define the following terms: bankruptcy law, Chapter 11, Chapter 7, trustee, voluntary bankruptcy, and involuntary bankruptcy.

How does a firm formally declare bankruptcy?

24-5 Reorganization in Bankruptcy (Chapter 11 of Bankruptcy Code)

It might appear that most reorganizations should be handled informally because informal reorganizations are faster and less costly than formal bankruptcy. However, two problems often arise to stymie informal reorganizations and thus force debtors into Chapter 11 bankruptcy: the common pool problem and the holdout problem.[4]

To illustrate these problems, consider a firm that is having financial difficulties. It is worth $9 million as a going concern (this is the present value of its expected future

[3]For a discussion of European bankruptcy laws, see Kevin M. J. Kaiser, "European Bankruptcy Laws: Implications for Corporations Facing Financial Distress," *Financial Management*, Autumn 1996, pp. 67–85.

[4]The issues discussed in this section are covered in more detail in Thomas H. Jackson, *The Logic and Limits of Bankruptcy Law* (Frederick, MD: Beard Group, 2001). Also see Stuart C. Gilson, "Managing Default: Some Evidence on How Firms Choose between Workouts and Chapter 11," *Journal of Applied Corporate Finance*, Summer 1991, pp. 62–70; and Yehning Chen, J. Fred Weston, and Edward I. Altman, "Financial Distress and Restructuring Models," *Financial Management*, Summer 1995, pp. 57–75.

operating cash flows) but only $7 million if it is liquidated. The firm's debt totals $10 million at face value—ten creditors with equal priority each have a $1 million claim. Now suppose the firm's liquidity deteriorates to the point that it defaults on one of its loans. The holder of that loan has the contractual right to *accelerate* the claim, which means the creditor can *foreclose* on the loan and demand payment of the entire balance. Further, because most debt agreements have *cross-default provisions*, defaulting on one loan effectively places all loans in default.

The firm's market value is less than the $10 million face value of debt, regardless of whether it remains in business or liquidates. Therefore, it would be impossible to pay off all of the creditors in full. However, the creditors in total would be better off if the firm is not shut down, because they could ultimately recover $9 million if the firm remains in business but only $7 million if it is liquidated. The problem here, which is called the **common pool problem**, is that in the absence of protection under the Bankruptcy Act, individual creditors would have an incentive to foreclose on the firm even though it is worth more as an ongoing concern.

An individual creditor would have the incentive to foreclose because it could then force the firm to liquidate a portion of its assets to pay off that particular creditor's $1 million claim in full. The payment to that creditor would probably require the liquidation of vital assets, which might cause a shutdown of the firm and thus lead to a total liquidation. Therefore, the value of the remaining creditors' claims would decline. Of course, all the creditors would recognize the gains they could attain from this strategy, so they would storm the debtor with foreclosure notices. Even those creditors who understand the merits of keeping the firm alive would be forced to foreclose, because the foreclosures of the other creditors would reduce the payoff to those who do not. In our hypothetical example, if seven creditors foreclosed and forced liquidation, they would be paid in full, and the remaining three creditors would receive nothing.

With many creditors, as soon as a firm defaults on one loan, there is the potential for a disruptive flood of foreclosures that would make the creditors collectively worse off. In our example, the creditors would lose $\$9 - \$7 = \$2$ million in value if a flood of foreclosures were to force the firm to liquidate. If the firm had only one creditor—say, a single bank loan—then the common pool problem would not exist. If a bank had loaned the company $10 million, it would not force liquidation to get $7 million when it could keep the firm alive and eventually realize $9 million.

Chapter 11 of the Bankruptcy Act provides a solution to the common pool problem through its **automatic stay** provision. *An automatic stay, which is forced on all creditors in a bankruptcy, limits the ability of creditors to foreclose to collect their individual claims.* However, the creditors can collectively foreclose on the debtor and force liquidation.

Although bankruptcy gives the firm a chance to work out its problems without the threat of creditor foreclosure, management does not have a completely free rein over the firm's assets. First, bankruptcy law requires the debtor firm to request permission from the court to take many actions, and the law also gives creditors the right to petition the bankruptcy court to block almost any action the firm might take while in bankruptcy. Second, **fraudulent conveyance** statutes, which are part of debtor–creditor law, protect creditors from unjustified transfers of property by a firm in financial distress.

To illustrate fraudulent conveyance, suppose a holding company is contemplating bankruptcy protection for one of its subsidiaries. The holding company might be tempted to sell some or all of the subsidiary's assets to itself (the parent company) for less than the true market value. This transaction would reduce the value of the subsidiary by the difference between the true market value of its assets and the amount paid, and the loss would be borne primarily by the subsidiary's creditors. Such a transaction would be voided by the courts as a fraudulent conveyance. Note also that transactions favoring

one creditor at the expense of another can be voided under the same law. For example, a transaction in which an asset is sold and the proceeds are used to pay one creditor in full at the expense of other creditors could be voided. Thus, fraudulent conveyance laws also protect creditors from each other.[5]

The second problem that is mitigated by bankruptcy law is the **holdout problem**. To illustrate this, consider again our example firm with ten creditors owed $1 million each but with assets worth only $9 million. The goal of the firm is to avoid liquidation by remedying the default. In an informal workout, this would require a reorganization plan that is agreed to by each of the ten creditors. Suppose the firm offers each creditor new debt with a face value of $850,000 in exchange for the old $1,000,000 face value debt. If each of the creditors accepted the offer, the firm could be successfully reorganized. The reorganization would leave the equity holders with some value—the market value of the equity would be $\$9{,}000{,}000 - 10(\$850{,}000) = \$500{,}000$. Further, the creditors would have claims worth $8.5 million, much more than the $7 million value of their claims in liquidation.

Although such an exchange offer seems to benefit all parties, it might not be accepted by the creditors. Here's why: Suppose seven of the ten creditors tender their bonds; thus, seven creditors each now have claims with a face value of $850,000 each, or $5,950,000 in total, while the three creditors that did not tender their bonds each still have a claim with a face value of $1 million. The total face value of the debt at this point is $8,950,000, which is less than the $9 million value of the firm. In this situation, the three holdout creditors would receive the full face value of their debt. However, this probably would not happen, for two reasons: (1) All of the creditors would be sophisticated enough to realize this could happen. (2) Each creditor would want to be one of the three holdouts that gets paid in full. Thus, it is likely that none of the creditors would accept the offer. The holdout problem makes it difficult to restructure the firm's debts. Again, if the firm had a single creditor, there would be no holdout problem.

The holdout problem is mitigated in bankruptcy proceedings by the bankruptcy court's ability to lump creditors into classes. Each class is considered to have accepted a reorganization plan if two-thirds of the amount of debt and one-half the number of claimants vote for the plan, and the plan will be approved by the court if it is deemed to be "fair and equitable" to the dissenting parties. This procedure, in which the court mandates a reorganization plan in spite of dissent, is called a **cramdown provision**, because the court crams the plan down the throats of the dissenters. The ability of the court to force acceptance of a reorganization plan greatly reduces the incentive for creditors to hold out. Thus, in our example, if the reorganization plan offered each creditor a new claim worth $850,000 in face value along with information that each creditor would probably receive only $700,000 under the liquidation alternative, then reorganization would have a good chance of success.

It is easier for a firm with few creditors to reorganize informally than it is for a firm with many creditors. A 1990 study examined 169 publicly traded firms that experienced severe financial distress from 1978 to 1987.[6] About half of the firms reorganized without filing for bankruptcy, while the other half were forced to reorganize in bankruptcy. The firms that reorganized without filing for bankruptcy owed most of their debt to a few banks and had fewer creditors. Generally, bank debt can be reorganized outside of bankruptcy, but a publicly traded bond issue held by thousands of individual bondholders makes reorganization difficult.

[5]The bankruptcy code requires that all transactions undertaken by the firm in the 6 months prior to a bankruptcy filing be reviewed by the court for fraudulent conveyance, and the review can go back as far as 3 years.

[6]See Stuart Gilson, Kose John, and Larry Lang, "Troubled Debt Restructurings: An Empirical Study of Private Reorganization of Firms in Default," *Journal of Financial Economics*, October 1990, pp. 315–354.

Filing for bankruptcy under Chapter 11 has several other features that help the bankrupt firm.

1. Interest and principal payments, including interest on delayed payments, may be delayed without penalty until a reorganization plan is approved, and the plan itself may call for even further delays. This permits cash generated from operations to be used to sustain operations rather than be paid to creditors.
2. The firm is permitted to issue **debtor-in-possession (DIP) financing**. DIP financing enhances the ability of the firm to borrow funds for short-term liquidity purposes, because such loans are, under the law, senior to all previous unsecured debt.
3. The debtor firm's managers are given the exclusive right for 120 days after filing for bankruptcy protection to submit a reorganization plan, plus another 60 days to obtain agreement on the plan from the affected parties. The court may also extend these dates up to 18 months. After management's first right to submit a plan has expired, any party to the proceedings may propose its own reorganization plan.

Under the early bankruptcy laws, most formal reorganization plans were guided by the **absolute priority doctrine**.[7] This doctrine holds that creditors should be compensated for their claims in a rigid hierarchical order and that senior claims must be paid in full before junior claims can receive even a dime. If there were any chance that a delay would lead to losses by senior creditors, then the firm would be shut down and liquidated. However, an alternative position, the **relative priority doctrine**, holds that more flexibility should be allowed in a reorganization and that a balanced consideration should be given to all claimants. The current law represents a movement away from absolute priority toward relative priority.

The primary role of the bankruptcy court in a reorganization is to determine the **fairness** and the **feasibility** of the proposed plan of reorganization. The basic doctrine of fairness states that claims must be recognized in the order of their legal and contractual priority. Feasibility means that there is a reasonable chance that the reorganized company will be viable. Carrying out the concepts of fairness and feasibility in a reorganization involves the following steps.

1. Future sales must be estimated.
2. Operating conditions must be analyzed so that future earnings and cash flows can be predicted.
3. The appropriate capitalization rate must be determined.
4. This capitalization rate must then be applied to the estimated cash flows to obtain an estimate of the company's value.[8]
5. An appropriate capital structure for the company after it emerges from Chapter 11 must be determined.
6. The reorganized firm's securities must be allocated to the various claimants in a fair and equitable manner.

---

Weiss, "The Bankruptcy Code and Violations of Absolute Priority," *Journal of Applied Corporate Finance*, Summer 1991, pp. 71–78; William Beranek, Robert Boehmer, and Brooke Smith, "Much Ado about Nothing: Absolute Priority Deviations in Chapter 11," *Financial Management*, Autumn 1996, pp. 102–109; and Allan C. Eberhart, William T. Moore, and Rodney Roenfeldt, "Security Pricing and Deviations from the Absolute Priority Rule in Bankruptcy Proceedings," *Journal of Finance*, December 1990, pp. 1457–1469.

[8]Several different approaches can be used to estimate a company's value. Market-determined multiples such as the price/earnings ratio, which are obtained from an analysis of comparable firms, can be applied to some measure of the company's earnings or cash flow. Alternatively, discounted cash flow techniques may be used. The key point here is that fairness requires the value of a company facing reorganization to be estimated so that potential offers can be evaluated rationally by the bankruptcy court.

The primary test of feasibility in a reorganization is whether the fixed charges after reorganization will be adequately covered by earnings. Adequate coverage generally requires an improvement in earnings, a reduction of fixed charges, or both. Among the actions that must generally be taken are the following:

1. Debt maturities are usually lengthened, interest rates may be lowered, and some debt is usually converted into equity.
2. When the quality of management has been substandard, a new team must be given control of the company.
3. If inventories have become obsolete or depleted, they must be replaced.
4. Sometimes the plant and equipment must be modernized before the firm can operate and compete successfully.
5. Reorganization may also require an improvement in production, marketing, advertising, and/or other functions.
6. It is sometimes necessary to develop new products or markets to enable the firm to move from areas where economic trends are poor into areas with more potential for growth.
7. Labor unions must agree to accept lower wages and less restrictive work rules. This was a major issue for United Airlines (UAL) in 2003 as it attempted to emerge from Chapter 11 bankruptcy protection. By threatening liquidation, UAL was able to squeeze a $6.6 billion reduction in payroll costs from its pilots over 6 years and another $2.6 billion from its ground-crew workers. This wasn't enough, though, and UAL didn't emerge from bankruptcy for another 3 years.

These actions usually require at least some new money, so most reorganization plans include new investors who are willing to put up capital.

It might appear that stockholders have very little to say in a bankruptcy situation in which the firm's assets are worth less than the face value of its debt. Under the absolute priority rule, stockholders in such a situation should get nothing of value under a reorganization plan. In fact, however, stockholders may be able to extract some of the firm's value due to three reasons: (1) Stockholders generally continue to control the firm during the bankruptcy proceedings. (2) Stockholders have the first right (after management's 120-day window) to file a reorganization plan. (3) For the creditors, developing a plan and taking it through the courts would be expensive and time-consuming. Given this situation, creditors may support a plan under which they are not paid off in full and where the old stockholders will control the reorganized company, because the creditors want to get the problem behind them and to get some money in the near future.

24-5a Illustration of a Reorganization

Reorganization procedures may be illustrated with an example involving the Columbia Software Company, a regional firm that specializes in selling, installing, and servicing accounting software for small businesses.[9] Table 24-2 gives Columbia's balance sheet as of March 31, 2016. The company had been suffering losses running to $2.5 million a year, and (as the following discussion will make clear) the asset values in the balance sheet were overstated relative to their market values. The firm was **insolvent**, which means that the book values of its liabilities were greater than the market values of its assets, so it filed a petition with a federal court for reorganization under Chapter 11. Management filed

[9]This example is based on an actual reorganization, although the company name has been changed and the numbers have been changed slightly to simplify the analysis.

TABLE 24-2
Columbia Software Company: Balance Sheet as of March 31, 2016 (Millions of Dollars)

Assets	
Current assets	$ 3.50
Net fixed assets	12.50
Other assets	0.70
Total assets	$16.70
Liabilities and Equity	
Accounts payable	$ 1.00
Accrued taxes	0.25
Notes payable	0.25
Other current liabilities	1.75
7.5% first-mortgage bonds, due 2024	6.00
9% subordinated debentures, due 2019[a]	7.00
Total liabilities	$16.25
Common stock ($1 par)	1.00
Paid-in capital	3.45
Retained earnings	(4.00)
Total liabilities and equity	$16.70

Note:

[a] The debentures are subordinated to the notes payable.

a plan of reorganization with the court on June 13, 2016. The plan was subsequently submitted for review by the SEC.[10]

The plan concluded that the company could not be internally reorganized and that the only feasible solution would be to combine Columbia with a larger, nationwide software company. Accordingly, management solicited the interest of a number of software companies. Late in July 2016, Moreland Software showed an interest in Columbia. On August 3, 2016, Moreland made a formal proposal to take over Columbia's $6 million of 7.5% first-mortgage bonds, to pay the $250,000 in taxes owed by Columbia, and to provide 40,000 shares of Moreland common stock to satisfy the remaining creditor claims. The Moreland stock had a market price of $75 per share, so the value of the stock was $3 million. Thus, Moreland was offering $3 million of stock plus assuming $6 million of loans and $250,000 of taxes—a total of $9.25 million for assets that had a book value of $16.7 million.

Moreland's plan is shown in Table 24-3. As in most Chapter 11 plans, the secured creditors' claims are paid in full (in this case, the mortgage bonds are taken over by Moreland Software). However, the total remaining unsecured claims equal $10 million against only $3 million of Moreland stock. Thus, each unsecured creditor would be entitled to receive 30% before the adjustment for subordination. Before this adjustment, holders of the notes payable would receive 30% of their $250,000 claim, or $75,000 in stock. However,

[10]Reorganization plans must be submitted to the Securities and Exchange Commission (SEC) if two conditions hold: (1) The securities of the debtor are publicly held. (2) Total indebtedness exceeds $3 million. However, in recent years the only bankruptcy cases that the SEC has become involved in are those that set precedent or involve issues of national interest.

TABLE 24-3
Columbia Software Company: Reorganization Plan

Panel A: Senior Claims

Senior Claimant	Amount	Result
Taxes	$ 250,000	Paid off by Moreland
Mortgage bonds	$6,000,000	Assumed by Moreland

The reorganization plan for the remaining $10 million of liabilities, based on 40,000 shares at a price of $75 for a total market value of $3 million, or 30% of the remaining liabilities, is as follows:

Panel B: Junior Claims

Claimant (1)	Original Amount (2)	30% of Claim Amount (3)	Claim after Subordination (4)	Number of Shares of Common Stock (5)	Percentage of Original Claim Received (6)
Notes payable	$ 250,000	$ 75,000	$ 250,000[a]	3,333	100%
Unsecured creditors	2,750,000	825,000	825,000	11,000	30
Subordinated debentures	7,000,000	2,100,000	1,925,000[a]	25,667	28
	$10,000,000	$3,000,000	$3,000,000	40,000	30

Note:

[a] Because the debentures are subordinated to the notes payable, $250,000 − $75,000 = $175,000 must be redistributed from the debentures to the notes payable; this leaves a claim of $2,100,000 − $175,000 = $1,925,000 for the debentures.

the debentures are subordinated to the notes payable, so an additional $175,000 must be allocated to notes payable (see footnote a in Table 24-3). In Column 5, the dollar claims of each class of debt are restated in terms of the number of shares of Moreland common stock received by each class of unsecured creditors. Finally, Column 6 shows the percentage of the original claim that each group received. Of course, both the taxes and the secured creditors were paid off in full, while the stockholders received nothing.[11]

The bankruptcy court first evaluated the proposal from the standpoint of fairness. The court began by considering the value of Columbia Software as estimated by the unsecured creditors' committee and by a subgroup of debenture holders. After discussions with various experts, one group had arrived at estimated post-reorganization sales of $25 million per year. It further estimated that the profit margin on sales would equal 6%, thus producing estimated future annual earnings of $1.5 million.

This subgroup analyzed price/earnings ratios for comparable companies and arrived at 8 times future earnings for a capitalization factor. Multiplying 8 by $1.5 million gave an indicated equity value of the company of $12 million. This value was 4 times that of the 40,000 shares of Moreland stock offered for the remainder of the company. Thus, the subgroup concluded that the plan for reorganization did not meet the test of fairness. Note that, under both Moreland's plan and the subgroup's plan, the holders of common stock were to receive nothing, which is one of the risks of ownership, while

[11] We do not show it, but $365,000 of fees for Columbia's attorneys and $123,000 of fees for the creditors' committee lawyers were also deducted. The current assets shown in Table 24-2 were net of these fees. Creditors joke (often bitterly) about the "lawyers first" rule in payouts in bankruptcy cases. It is often said, with much truth, that the only winners in bankruptcy cases are the attorneys.

the holders of the first-mortgage bonds were to be assumed by Moreland, which amounts to being paid in full.

The bankruptcy judge examined management's plan for feasibility, observing that in the reorganization Moreland Software would take over Columbia's properties. The court judged that the direction and aid that Moreland could offer would remedy the deficiencies that had troubled Columbia. Whereas the debt/assets ratio of Columbia Software had become unbalanced, Moreland had only a moderate amount of debt. After consolidation, Moreland would still have a relatively low 27% debt ratio.

Moreland's net income before interest and taxes had been running at a level of approximately $15 million. The interest on its long-term debt after the merger would be $1.5 million and, taking short-term borrowings into account, would total a maximum of $2 million per year. The $15 million in earnings before interest and taxes would therefore provide an interest charge coverage of 7.5 times, exceeding the norm of 5 times for the industry.

Note that the question of feasibility would have been irrelevant if Moreland had offered $3 million in cash (rather than in stock) and payment of the bonds (rather than assuming them). It is the court's responsibility to protect the interests of Columbia's creditors. Because the creditors are being forced to take common stock or bonds guaranteed by another firm, the law requires the court to look into the feasibility of the transaction. However, if Moreland had made a cash offer, then the feasibility of its own operation after the transaction would not have been a concern.

Moreland Software was told of the subgroup's analysis and concern over the fairness of the plan. Further, Moreland was asked to increase the number of shares it offered. Moreland refused, and no other company offered to acquire Columbia. Because no better offer could be obtained and the only alternative to the plan was liquidation (with an even lower realized value), Moreland's proposal was ultimately accepted by the creditors despite some disagreement with the valuation.

One interesting aspect of this case concerned an agency conflict between Columbia's old stockholders and its management. Columbia's management knew when it filed for bankruptcy that the company was probably worth less than the amount of its debt and hence that stockholders would probably receive nothing. Indeed, that situation did materialize. If management has a primary responsibility to the stockholders, then why would it file for bankruptcy knowing that the stockholders would receive nothing? In the first place, management did not know for certain that stockholders would receive nothing. But they were certain that, if they did not file for bankruptcy protection, then creditors would foreclose on the company's property and shut the company down, which would surely lead to liquidation and a total loss to stockholders. Second, if the company were liquidated, then managers and workers would lose their jobs and the managers would have a black mark on their records. Finally, Columbia's managers thought (correctly) that there was nothing they could do to protect the stockholders, so they might as well do what was best for the workforce, the creditors, and themselves—and that meant realizing the most value possible for the company's assets.

Some of the stockholders felt betrayed by management—they thought management should have taken more heroic steps to protect them, regardless of the cost to other parties. One stockholder suggested management should have sold off assets, taken the cash to Las Vegas, and rolled the dice. Then, if they won, they should have paid off the debt and had something left for stockholders, leaving debtholders holding the bag if they lost. Actually, management had done something a bit like this in the year preceding the bankruptcy. Management realized the company was floundering, was likely to sink under its current operating plan, and that only a "big winner" project would save the company. Hence, they took on several risky, "bet the company" projects with negative expected NPVs but at least some chance for high profits. Unfortunately, those projects did not work out.

24-5b Prepackaged Bankruptcies

One type of reorganization combines the advantages of both the informal workout and formal Chapter 11 reorganization. This hybrid is called a **prepackaged bankruptcy**, or **pre-pack**.[12]

In an informal workout, a debtor negotiates a restructuring with its creditors. Even though complex workouts typically involve corporate officers, lenders, lawyers, and investment bankers, workouts are still less expensive and less damaging to reputations than are Chapter 11 reorganizations. In a prepackaged bankruptcy, the debtor firm gets all, or most, of the creditors to agree to the reorganization plan *prior* to filing for bankruptcy. Then, a reorganization plan is filed along with, or shortly after, the bankruptcy petition. If enough creditors have signed on before the filing, a cramdown can be used to bring reluctant creditors along.

A logical question arises: Why would a firm that can arrange an informal reorganization want to file for bankruptcy? The three primary advantages of a prepackaged bankruptcy are: (1) reduction of the holdout problem, (2) preserving creditors' claims, and (3) taxes. Perhaps the biggest benefit of a prepackaged bankruptcy is the reduction of the holdout problem, because a bankruptcy filing permits a cramdown that would otherwise be impossible. By eliminating holdouts, bankruptcy forces all creditors in each class to participate on a pro rata basis, which preserves the relative value of all claimants. Also, filing for formal bankruptcy can at times have positive tax implications. First, in an informal reorganization in which the debtholders trade debt for equity, if the original equity holders end up with less than 50% ownership then the company loses its accumulated tax losses. In formal bankruptcy, in contrast, the firm may get to keep its loss carryforwards. Second, in a workout, when (say) debt worth $1,000 is exchanged for debt worth $500, the reduction in debt of $500 is considered to be taxable income to the corporation. However, if this same situation occurs in a Chapter 11 reorganization, the difference is not treated as taxable income.[13]

All in all, prepackaged bankruptcies make sense in many situations. If sufficient agreement can be reached among creditors through informal negotiations, a subsequent filing can solve the holdout problem and result in favorable tax treatment. For these reasons, the number of prepackaged bankruptcies has grown dramatically in recent years.

24-5c Reorganization Time and Expense

The time, expense, and headaches involved in a reorganization are almost beyond comprehension. Even in a small bankruptcy, such as one with assets valued between $2 million and $5 million, many people and groups are involved: lawyers representing the company, the U.S. Bankruptcy Trustee, each class of secured creditor, the general creditors as a group, tax authorities, and the stockholders if they are upset with management. There are time limits within which things are supposed to be done, but the process generally takes at least a year and usually much longer. The company must be given time to file its plan, and creditor groups must be given time to study and seek clarifications to it and then file counterplans, to which the company must respond. Also, different creditor classes often disagree among themselves as to how much each class should receive, and hearings must be held to resolve such conflicts.

---

[12]For more information on prepackaged bankruptcies, see John J. McConnell and Henri Servaes, "The Economics of Pre-Packaged Bankruptcy," *Journal of Applied Corporate Finance*, Summer 1991, pp. 93–97; Brian L. Betker, "An Empirical Examination of Prepackaged Bankruptcy," *Financial Management*, Spring 1995, pp. 3–18; Sris Chatterjee, Upinder S. Dhillon, and Gabriel G. Ramirez, "Resolution of Financial Distress: Debt Restructurings via Chapter 11, Prepackaged Bankruptcies, and Workouts," *Financial Management*, Spring 1996, pp. 5–18; and John J. McConnell, Ronald C. Lease, and Elizabeth Tashjian, "Prepacks as a Mechanism for Resolving Financial Distress," *Journal of Applied Corporate Finance*, Winter 1996, pp. 99–106.

[13]Note that in both tax situations—loss carryforwards and debt value reductions—favorable tax treatment can be available in workouts if the firm is deemed to be legally insolvent—that is, if the market value of its assets is demonstrated to be less than the face value of its liabilities.

Management will want to remain in business, whereas some well-secured creditors may want the company liquidated as quickly as possible. Often, some party's plan will involve selling the business to another concern, as was the case with Columbia Software in our earlier example. Obviously, it can take months to seek out and negotiate with potential merger candidates.

The typical bankruptcy case takes about 2 years from the time the company files for protection under Chapter 11 until the final reorganization plan is approved or rejected. While all of this is going on, the company's business suffers. Sales certainly won't be helped, key employees may leave, and the remaining employees will be worrying about their jobs rather than concentrating on their work. Further, management will be spending much of its time on the bankruptcy rather than running the business, and it won't be able to take any significant action without court approval, which requires filing a formal petition with the court and giving all parties involved a chance to respond.

Even if its operations do not suffer, the company's assets surely will be reduced by its own legal fees and the required court and trustee costs. Good bankruptcy lawyers charge from $200 to $400 or more per hour, depending on the location, so those costs are not trivial. The creditors also will be incurring legal costs. Indeed, the sound of all of those meters ticking at $400 or so an hour in a slow-moving hearing can be deafening.

Note that creditors also lose the time value of their money. A creditor with a $100,000 claim and a 10% opportunity cost who ends up getting $50,000 after 2 years would have been better off settling for $41,500 initially. When the creditor's legal fees, executive time, and general aggravation are taken into account, it might make sense to settle for $25,000 or even $20,000.

Both the troubled company and its creditors know the drawbacks of formal bankruptcy, or their lawyers will inform them. Armed with knowledge of how bankruptcy works, management may be in a strong position to persuade creditors to accept a workout that may seem to be unfair and unreasonable. Or, if a Chapter 11 case has already begun, creditors may at some point agree to settle just to stop the bleeding.

One final point should be made before closing this section. In most reorganization plans, creditors with claims of less than $1,000 are paid off in full. Paying off these "nuisance claims" does not cost much money, and it saves time and gets votes to support the plan.[14]

SELF-TEST

Define the following terms: common pool problem, holdout problem, automatic stay, cramdown, fraudulent conveyance, absolute priority doctrine, relative priority doctrine, fairness, feasibility, debtor-in-possession financing, and prepackaged bankruptcy.

What are the advantages of a formal reorganization under Chapter 11?

What are some recent trends regarding absolute versus relative priority doctrines?

How do courts assess the fairness and feasibility of reorganization plans?

Why have prepackaged bankruptcies become so popular in recent years?

24-6 Liquidation in Bankruptcy

If a company is "too far gone" to be reorganized, then it must be liquidated. Liquidation should occur when the business is worth more dead than alive, or when the possibility of restoring it to financial health is remote and the creditors are exposed to a high risk of

[14]For more information on bankruptcy costs, see Daryl M. Guffey and William T. Moore, "Direct Bankruptcy Costs: Evidence from the Trucking Industry," *The Financial Review*, May 1991, pp. 223–235.

greater loss if operations are continued. Earlier we discussed assignment, which is an informal liquidation procedure. Now we consider **liquidation in bankruptcy**, which is carried out under the jurisdiction of a federal bankruptcy court.

Chapter 7 of the Federal **Bankruptcy Reform Act of 1978** deals with liquidation. It: (1) provides safeguards against fraud by the debtor, (2) provides for an equitable distribution of the debtor's assets among the creditors, and (3) allows insolvent debtors to discharge all their obligations and thus be able to start new businesses unhampered by the burdens of prior debt. However, formal liquidation is time-consuming and costly, and it extinguishes the business.

The distribution of assets under Chapter 7 is governed by the following **priority of claims in liquidation**.[15]

1. *Past-due property tax liens.*[16]
2. *Secured creditors, who are entitled to the proceeds of the sale of specific property pledged for a lien or a mortgage.* If the proceeds from the sale of the pledged property do not fully satisfy a secured creditor's claim, the remaining balance is treated as a general creditor claim (see Item 10 below).[17]
3. *Legal fees and other expenses to administer and operate the bankrupt firm.* These costs include legal fees incurred in trying to reorganize.
4. *Expenses incurred after an involuntary case has begun but before a trustee is appointed.*
5. *Wages due workers if earned within 180 days prior to the filing of the petition for bankruptcy.* The amount of wages is limited to $11,725 per employee.
6. *Claims for unpaid contributions to employee pension plans that should have been paid within 180 days prior to filing.* These claims, plus wages in Item 5, may not exceed the limit of $11,725 per wage earner.
7. *Unsecured claims for customer deposits.* These claims are limited to a maximum of $2,600 per individual.
8. *Taxes due to federal, state, county, and other government agencies.*
9. *Unfunded pension plan liabilities.* These liabilities have a claim above that of the general creditors for an amount up to 30% of the common and preferred equity, and any remaining unfunded pension claims rank with the general creditors.[18]

[15]See **www.law.cornell.edu/uscode/text/11/507** for a complete listing of the priority of claims.

[16]See **www.law.cornell.edu/uscode/text/11/724** for the priority rules regarding liens.

[17]When a firm or individual who goes bankrupt has a bank loan, the bank will attach any deposit balances. The loan agreement may stipulate that the bank has a first-priority claim on any deposits. If so, then the deposits are used to offset all or part of the bank loan—in legal terms, "the right of offset." In this case, the bank will not have to share the deposits with other creditors. Loan contracts often designate compensating balances as security against a loan. Even if the bank has no explicit claim against deposits, the bank will attach the deposits and hold them for the general body of creditors, including the bank itself. Without an explicit statement in the loan agreement, the bank does not receive preferential treatment with regard to attached deposits.

[18]Pension plan liabilities have a significant bearing on bankruptcy settlements. As we discuss in ***Web Chapter 29,*** pension plans may be funded or unfunded. With a *funded* plan, the firm makes cash payments to an insurance company or to a trustee (generally a bank), which then uses these funds (and the interest earned on them) to pay retirees' pensions. With an *unfunded* plan, the firm is obligated to make payments to retirees, but it does not provide cash in advance. Many plans are actually partially funded—some money has been paid in advance but not enough to provide full pension benefits to all employees.

If a firm goes bankrupt, the funded part of the pension plan remains intact and is available for retirees. Prior to 1974, employees had no explicit claims for unfunded pension liabilities, but under the Employees' Retirement Income Security Act of 1974 (ERISA), an amount up to 30% of the equity (common and preferred) is earmarked for employees' pension plans and has a priority over the general creditors, with any remaining pension claims having status equal to that of the general creditors. This means, in effect, that the funded portion of a bankrupt firm's pension plan is completely secured, whereas the unfunded portion ranks just above the general creditors. Obviously, unfunded pension liabilities should be of great concern to a firm's unsecured creditors.

TABLE 24-4
Whitman Inc.: Balance Sheet at Liquidation (Millions of Dollars)

Current assets	$80.0	Accounts payable	$20.0
Net fixed assets	10.0	Notes payable (to banks)	10.0
		Accrued wages (1,400 @ $500)	0.7
		Federal taxes	1.0
		State and local taxes	0.3
		Current liabilities	$32.0
		First mortgage	6.0
		Second mortgage	1.0
		Subordinated debentures[a]	8.0
		Total long-term debt	$15.0
		Preferred stock	2.0
		Common stock	26.0
		Paid-in capital	4.0
		Retained earnings	11.0
		Total equity	$43.0
Total assets	$90.0	Total liabilities and equity	$90.0

Note:

[a] The debentures are subordinated to the notes payable.

10. *General, or unsecured, creditors*. Holders of trade credit, unsecured loans, the unsatisfied portion of secured loans, and debenture bonds are classified as general creditors. Holders of subordinated debt also fall into this category, but they must turn over required amounts to the senior debt.
11. *Preferred stockholders*. These stockholders can receive an amount up to the par value of their stock.
12. *Common stockholders*. These stockholders receive any remaining funds.[19]

To illustrate how this priority system works, consider the balance sheet of Whitman Inc., shown in Table 24-4. Assets have a book value of $90 million. The claims are shown on the right-hand side of the balance sheet. Note that the debentures are subordinated to the notes payable to banks. Whitman filed for bankruptcy under Chapter 11, but because no fair and feasible reorganization could be arranged, the trustee is liquidating the firm under Chapter 7.

The assets as reported in the balance sheet are greatly overstated; they are, in fact, worth less than half the $90 million that is shown. The following amounts are realized on liquidation:

From sale of current assets	$28,000,000
From sale of fixed assets	5,000,000
Total receipts	$33,000,000

[19] Note that if different classes of common stock have been issued, then differential priorities may exist in stockholder claims.

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The distribution of proceeds from the liquidation is shown in Table 24-5. The first-mortgage holders receive the $5 million in net proceeds from the sale of fixed property, leaving $28 million available to the remaining creditors, including a $1 million unsatisfied claim of the first-mortgage holders. Next are the fees and expenses of administering the bankruptcy, which are typically about 20% of gross proceeds (including the bankrupt firm's own legal fees); in this example, they are assumed to be $6 million. Next in priority are wages due workers, which total $700,000, and taxes due, which amount to $1.3 million. Thus far, the total amount of claims paid from the $33 million received from the asset sale is $13 million, leaving $20 million for the general creditors. In this example, we assume there are no claims for unpaid benefit plans or unfunded pension liabilities.

The claims of the general creditors total $40 million. Because $20 million is available, claimants will be allocated 50% of their claims initially, as shown in Column 3. However, the subordination adjustment requires that the subordinated debentures turn over to the notes payable all amounts received until the notes are satisfied. In this situation, the claim of the notes payable is $10 million but only $5 million is available; the deficiency is therefore $5 million. After transfer of $4 million from the subordinated debentures, there remains a deficiency of $1 million on the notes; this amount will remain unsatisfied.

TABLE 24-5
Whitman Inc.: Distribution of Liquidation Proceeds (Millions of Dollars)

Panel A: Distribution to Priority Claimants	
Proceeds from the sale of assets	$33.0
Less:	
1. First mortgage (paid from the sale of fixed assets)	5.0
2. Fees and expenses of bankruptcy	6.0
3. Wages due to workers within 3 months of bankruptcy	0.7
4. Taxes due to federal, state, and local governments	1.3
Funds available for distribution to general creditors	$20.0

	Panel B: Distribution to General Creditors			
General Creditors' Claims (1)	**Amount of Claim[a] (2)**	**Pro Rata Distribution[b] (3)**	**Distribution after Subordination Adjustment[c] (4)**	**Percentage of Original Claim Received[d] (5)**
Unsatisfied portion of first mortgage	$ 1.0	$ 0.5	$ 0.5	92%
Second mortgage	1.0	0.5	0.5	50
Notes payable (to banks)	10.0	5.0	9.0	90
Accounts payable	20.0	10.0	10.0	50
Subordinated debentures	8.0	4.0	0.0	0
Total	$40.0	$20.0	$20.0	

Notes:

[a] Column 2 is the claim of each class of general creditor. Total claims equal $40.0 million.

[b] From the top section of the table, we see that $20 million is available for distribution to general creditors. Because there is $40 million worth of general creditor claims, the pro rata distribution will be $20/$40 = 0.50, or 50 cents on the dollar.

[c] The debentures are subordinate to the notes payable, so up to $5 million could be reallocated from debentures to notes payable. However, only $4 million is available to the debentures, so this entire amount is reallocated.

[d] Column 5 shows the results of dividing the Column 4 final allocation by the original claim shown in Column 2—except for the first mortgage, where the $5 million received from the sale of fixed assets is included in the calculation.

A Nation of Defaulters?

Big corporate bankruptcies like those of Lehman Brothers and General Motors get the headlines, but they represent a small portion of the many bankruptcies each year, as shown in the accompanying table. Most business bankruptcies are liquidations (Chapter 7) of small businesses, and they rose steadily from 2006 through 2009 and then have declined steadily since then. Although there are fewer business reorganizations than liquidations, reorganizations also increased steadily from 2006 through 2009 and have declined steadily since then, with the overall level of business bankruptcy filings now about equal to their pre-financial crisis levels.

Personal bankruptcies can be liquidations (Chapter 7) or reorganizations (Chapter 13). In a Chapter 7 bankruptcy, an individual can keep a small amount of exempt personal property, and the nonexempt property is sold to satisfy creditors. In a Chapter 13 bankruptcy, an individual is allowed to keep nonexempt personal property but typically must repay the debt within 3 to 5 years. A change in bankruptcy laws in 2005 made it more difficult for individuals to declare bankruptcy. Personal bankruptcies increased dramatically during the lead up to and following the financial crisis, with liquidations leading the way—they have yet to recover to pre-crisis levels.

Napoleon Bonaparte reputedly scorned England as "a nation of shopkeepers." If he had been able to see current U.S. bankruptcy statistics, would he have called modern America "a nation of defaulters"?

	Business					Personal			
Year	Ch. 7	Ch. 11	Ch. 12	Ch. 13	Total	Ch. 7	Ch. 11	Ch. 13	Total
2014	18,184	6,093	360	2,278	26,983	600,885	1,141	307,783	909,812
2013	22,334	7,660	395	2,727	33,212	706,499	1,320	330,899	1,038,720
2012	27,274	8,900	512	3,252	40,075	816,271	1,461	363,280	1,181,016
2011	33,698	9,772	637	3,630	47,806	958,634	1,757	402,454	1,362,847
2010	39,485	11,774	723	4,174	56,282	1,100,116	1,939	434,739	1,536,799
2009	41,962	13,683	544	4,500	60,837	1,008,870	1,506	402,462	1,412,838
2008	30,035	9,272	345	3,815	43,546	714,389	888	358,947	1,074,225
2007	18,751	5,736	376	3,412	28,322	500,613	617	321,359	822,590
2006	11,878	4,643	348	2,749	19,695	349,012	520	248,430	597,965
2005	28,006	5,923	380	4,808	39,201	1,631,011	877	407,322	2,039,214
2004	20,192	9,186	108	4,701	34,317	1,117,766	946	444,428	1,563,145

Source: **www.uscourts.gov/Statistics/BankruptcyStatistics.aspx.**

Note that 90% of the bank claim is satisfied, whereas a maximum of 50% of other unsecured claims will be satisfied. These figures illustrate the usefulness of the subordination provision to the security to which the subordination is made.

Because no other funds remain, the claims of the holders of preferred and common stocks, as well as the subordinated debentures, are completely wiped out. Studies of the proceeds in bankruptcy liquidations reveal that unsecured creditors receive, on the average, about 15 cents on the dollar, while common stockholders generally receive nothing.

SELF-TEST

Describe briefly the priority of claims in a formal liquidation.

What is the impact of subordination on the final allocation of proceeds from liquidation?

In general, how much do unsecured creditors receive from a liquidation? How much do stockholders receive?

24-7 Anatomy of a Bankruptcy: Transforming the GM *Corporation* into the GM *Company*

The General Motors *Corporation* was started in 1908 and became the world's largest automobile manufacturer, a distinction it held from 1931 until 2008. Despite its size and market power, GM lost a cumulative $82 billion from 2005 until 2008 and declared bankruptcy in 2009. Several factors contributed to GM's problems, including increased international competition, high costs associated with labor contracts (especially retirement benefits), the economic slowdown that began in 2007, and senior executives that the press labeled as out of touch.

A look at GM's financial statements reveals some of the major restructuring efforts prior to the bankruptcy. During the 1980s, GM became a major player in the financial services industries, and by 2005 its financing and insurance operations had assets of $312 billion, while its automotive business had assets of $162 billion. By this measure, GM was a "bank" with an auto manufacturer and not an auto company with a "bank." To refocus on its auto businesses and raise some cash in 2006, GM cut its dividend in half and sold a 51% stake of its financing company, GMAC, reducing its non-auto assets by about $290 billion to $22 billion. GM also sold its stakes in several other auto manufacturers in 2006 and 2007, to generate cash and to focus on its primary product line. With declining sales and profits, GM also closed factories and reduced its workforce.

When GM and the United Auto Workers (UAW) were unable to reach a contract agreement in 2007, the UAW called a strike. After two days, GM and the UAW reached an agreement. In exchange for a lower wage structure, GM agreed to create a trust fund (a voluntary employees' beneficiary association, called a VEBA) that would be managed by the UAW and that would fund retiree health care coverage. The liabilities associated with the retiree health care were estimated to be over $50 billion. GM agreed to put about $35 billion of assets into the VEBA (GM and the UAW assumed that the trust's $35 billion in assets would grow faster than the $50 billion in liabilities) and make the majority of its future contributions in the form of GM stock rather than cash.

GM continued to lose money. In late 2008, the CEOs of GM, Chrysler, and Ford flew to Washington in private jets to ask for government assistance. Congress was unable to agree on a plan, so the Bush administration broadened the Trouble Asset Relief Program (TARP) to include the auto industry. GM received a loan of $13.4 billion in December 2008. GMAC also received a TARP loan ($6 billion), as did Chrysler and its financial subsidiary. These loans required GM and Chrysler to submit turnaround plans to the government by February 17, 2009.[20]

A task force from the Obama administration reviewed the plans, rejected them, and gave GM and Chrysler an opportunity to revise the plans. The task force also asked for and received the resignation of Rick Wagoner, GM's CEO. In addition, the government provided loans to GM and Chrysler, loans to their suppliers (who were reluctant to keep selling to the auto companies on credit), and created a program to ensure that customer warranty claims would be honored.

GM was unable to provide a turnaround plan that was acceptable to its debtholders, suppliers, dealers, and workforce, so it filed for Chapter 11 bankruptcy protection on June 1, 2009. GM's bankruptcy petition listed its assets and liabilities as of its most recent 10-Q filing for the quarter ending March 31, 2009. It was not a pretty picture. GM listed

[20]For a detailed treatment of the government's involvement in GM's bankruptcy, see a paper by Thomas H. Klier and James Rubenstein, "Detroit Back from the Brink? Auto Industry Crisis and Restructuring, 2008–11," *Economic Perspectives*, 2Q/2012, pp. 35–54.

$82 billion in assets, but more than twice that amount ($173 billion) in liabilities, including short-term debt of $26 billion, long-term debt of $29 billion, and retiree obligations of $47 billion.

Two days after filing for bankruptcy, TARP provided an additional $30 billion; because GM had filed for bankruptcy, this loan was debtor-in-possession financing (DIP). In total, TARP provided about $50 billion in financing to GM.

On July 10, 2009, GM emerged from bankruptcy as a new company—literally! GM and its creditors agreed to sell almost all of GM's assets to a new company, to be named the General Motors Company (instead of Corporation). In return, GM's creditors and stakeholders exchanged their old claims for new claims in the new GM Company. GM now had about less than $16 billion in debt (compared to $55 billion before the bankruptcy) and $36 billion in retiree obligations (down from $47 billion). In addition to a much lower debt load, the bankruptcy plan called for GM to close over 10 factories, reduce the number of brands it sells, and reduce the number of its dealers.

GM emerged from bankruptcy with about $75 billion less in liabilities. What happened to all those claims? Senior secured loans and suppliers were paid in full. Subordinated bondholders were treated as senior unsecured debt and received about 1/8 the face value of their bonds. The common stockholders received nothing. As for other claimants, they received common stock in the new GM. The U.S. government received about 61% of the stock, the Canadian government received 11.7%, the VEBA trust received 17.5% (instead of the cash it was originally owed), and unsecured bondholders received 10%.

GM's shares were not publicly traded until November 18, 2010, when GM sold $20.1 billion in its IPO. GM's underwriters sold an additional $3 billion of stock, for a total of $23.1 billion, which made GM's IPO the biggest ever. GM didn't raise any cash in the IPO—all the shares were sold by existing stockholders, including the U.S. government, which reduced its ownership to about 33% of GM.

GM has been profitable since the IPO, but its stock price has been volatile, at one point falling to $19 from the IPO price of $33. The price eventually climbed past the IPO price but has lagged the stock market as a whole. In December 2013, the U.S. government sold the last of its GM stock, losing about $10 billion in the bailout.

SELF-TEST

What events preceded GM's bankruptcy?

What happened to the pre-bankruptcy stockholders and the claims of creditors?

24-8 Other Motivations for Bankruptcy

Normally, bankruptcy proceedings do not commence until a company has become so financially weak that it cannot meet its current obligations. However, bankruptcy law also permits a company to file for bankruptcy if its financial forecasts indicate that a continuation of current conditions would lead to insolvency.

Bankruptcy law has also been used to hasten settlements in major product liability suits. The Manville asbestos case is an example. Manville was being bombarded by thousands of lawsuits, and the very existence of such huge contingent liabilities made normal operations impossible. Further, it was relatively easy to demonstrate four salient facts: (1) If the plaintiffs won, the company would be unable to pay the full amount of the claims. (2) A larger amount of funds would be available to the claimants if the company continued to operate rather than liquidate. (3) Continued operations were possible only if the suits were brought to a conclusion. (4) A timely resolution of all the suits was impossible because of their vast number and variety.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Manville filed for bankruptcy in 1982, at that time the largest U.S. bankruptcy ever. The bankruptcy statutes were used to consolidate all the suits and to reach settlements under which the plaintiffs obtained more money than they otherwise would have received, and Manville was able to stay in business. (It was acquired in 2001 by Berkshire Hathaway.) The stockholders did poorly under these plans because most of the companies' future cash flows were assigned to the plaintiffs, but even so, the stockholders probably fared better than they would have if the suits had been concluded through the jury system.

SELF-TEST

What are some situations other than immediate financial distress that lead firms to file for bankruptcy?

24-9 Some Criticisms of Bankruptcy Laws

Although bankruptcy laws exist, for the most part, to protect creditors, many critics claim that current laws are not doing what they were intended to do. Before 1978, most bankruptcies ended quickly in liquidation. Then Congress rewrote the laws, giving companies more opportunity to stay alive on the grounds that this was best for managers, employees, creditors, and stockholders. Before the reform, 90% of Chapter 11 filers were liquidated, but now that percentage is less than 80%, and the average time between filing and liquidation has almost doubled. Indeed, large public corporations with the ability to hire high-priced legal help can avoid (or at least delay) liquidation, often at the expense of creditors and shareholders.

Critics believe that bankruptcy is great for businesses these days—especially for consultants, lawyers, and investment bankers, who reap hefty fees during bankruptcy proceedings, and for managers, who continue to collect their salaries and bonuses as long as the business is kept alive. The problem, according to critics, is that bankruptcy courts allow cases to drag on too long, depleting assets that could be sold to pay off creditors and shareholders. Too often, quick resolution is impossible because bankruptcy judges are required to deal with issues such as labor disputes, pension plan funding, and environmental liability—social questions that could be solved by legislative action rather than by bankruptcy courts.

Critics contend that bankruptcy judges ought to realize that some sick companies should be allowed to die—and die quickly. Maintaining companies on life support does not serve the interests of the parties that the bankruptcy laws were designed to protect. The 2005 changes to the bankruptcy code addressed this issue by limiting to 18 months the time that management has to file a reorganization plan. Prior to the change, judges could extend this time almost indefinitely. Now, creditors may propose a plan if an acceptable plan hasn't been filed by management within 18 months.

Other critics think the entire bankruptcy system of judicial protection and supervision needs to be scrapped. Some even have proposed an auction-like procedure, where shareholders and creditors would have the opportunity to gain control of a bankrupt company by raising the cash needed to pay the bills. The rationale here is that the market is a better judge than a bankruptcy court as to whether a company is worth more dead or alive.

SELF-TEST

According to critics, what are some problems with the bankruptcy system?

SUMMARY

This chapter discussed the main issues involved in bankruptcy and financial distress in general. The key concepts are listed here.

- The fundamental issue that must be addressed when a company encounters financial distress is whether it is "worth more dead than alive"; that is, would the business be more valuable if it continued in operation or if it were liquidated and sold off in pieces?
- In the case of a fundamentally sound company whose financial difficulties appear to be temporary, creditors will frequently work directly with the company, helping it to recover and reestablish itself on a sound financial basis. Such voluntary reorganization plans are called **workouts**.
- Reorganization plans usually require some type of **restructuring** of the firm's debts; this may involve an **extension**, which postpones the date of required payment of past-due obligations, and/or a **composition**, by which the creditors voluntarily reduce their claims on the debtor or the interest rate on their claims.
- When it is obvious that a firm is worth more dead than alive, informal procedures can sometimes be used to **liquidate** the firm. **Assignment** is an informal procedure for liquidating a firm, and it usually yields creditors a larger amount than they would receive in a formal bankruptcy liquidation. However, assignments are feasible only if the firm is small and its affairs are not too complex.
- Current **bankruptcy law** consists of nine chapters, designated by Arabic numbers. For businesses, the most important chapters are **Chapter 7**, which details the procedures to be followed when liquidating a firm, and **Chapter 11**, which contains procedures for formal reorganizations.
- Since the first bankruptcy laws, the **absolute priority doctrine** has guided most formal reorganization plans. This doctrine holds that creditors should be compensated for their claims in a rigid hierarchical order and that senior claims must be paid in full before junior claims can receive even a dime.
- Another position, the **relative priority doctrine**, holds that more flexibility should be allowed in a reorganization and that a balanced consideration should be given to all claimants. In recent years, there has been a shift away from absolute priority toward relative priority. The primary effect of this shift has been to delay liquidations, giving managements more time to rehabilitate companies in an effort to provide value to junior claimants.
- The primary role of the bankruptcy court in a reorganization is to determine the **fairness** and the **feasibility** of proposed plans of reorganization.
- Even if some creditors or stockholders dissent and do not accept a reorganization plan, the plan may still be approved by the court if the plan is deemed to be "fair and equitable" to all parties. This procedure, in which the court mandates a reorganization plan in spite of dissent, is called a **cramdown**.
- A **prepackaged bankruptcy** (also called a **pre-pack**) is a hybrid type of reorganization that combines the advantages of both an informal workout and a formal Chapter 11 reorganization.
- The distribution of assets in a **liquidation** under Chapter 7 of the Bankruptcy Act is governed by a specific priority of claims.
- **Multiple discriminant analysis (MDA)** is a method to identify firms with high bankruptcy risk. We discuss MDA in ***Web Extension 24A.***

QUESTIONS

(24-1) Define each of the following terms:

a. Informal restructuring; reorganization in bankruptcy
b. Assignment; liquidation in bankruptcy; fairness; feasibility
c. Absolute priority doctrine; relative priority doctrine
d. Bankruptcy Reform Act of 1978; Chapter 11; Chapter 7
e. Priority of claims in liquidation
f. Extension; composition; workout; cramdown; prepackaged bankruptcy; holdout

(24-2) Why do creditors usually accept a plan for financial rehabilitation rather than demand liquidation of the business?

(24-3) Would it be a sound rule to liquidate whenever the liquidation value is above the value of the corporation as a going concern? Discuss.

(24-4) Why do liquidations usually result in losses for the creditors or the owners, or both? Would partial liquidation or liquidation over a period limit their losses? Explain.

(24-5) Are liquidations likely to be more common for public utility, railroad, or industrial corporations? Why or why not?

SELF-TEST PROBLEM

Solution Shown in Appendix A

(ST-1) **Liquidation**

At the time it defaulted on its interest payments and filed for bankruptcy, Medford Fabricators Inc. had the following balance sheet (in millions of dollars). The court, after trying unsuccessfully to reorganize the firm, decided that the only recourse was liquidation under Chapter 7. Sale of the fixed assets, which were pledged as collateral to the mortgage bondholders, brought in $750 million, while the current assets were sold for another $400 million. Thus, the total proceeds from the liquidation sale were $1,150 million. The trustee's costs amounted to $1 million; no single worker was due more than the maximum allowable wages per worker; and there were no unfunded pension plan liabilities.

Current assets	$ 800	Accounts payable	$ 100
		Accrued taxes	90
		Accrued wages	60
		Notes payable	300
		Total current liabilities	$ 550
Net fixed assets	1,100	First-mortgage bonds[a]	700
		Second-mortgage bonds[a]	400
		Debentures	500
		Subordinated debentures[b]	200
		Common stock	100
		Retained earnings	(550)
Total assets	$1,900	Total claims	$1,900

Notes:

[a]All fixed assets are pledged as collateral to the mortgage bonds.

[b]Subordinated to notes payable.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

a. How much of the proceeds from the sale of assets remains to be distributed to general creditors after distribution to priority claimants?
b. After distribution to general creditors and subordination adjustments are made, how much of the proceeds are received by the second-mortgage holders? By holders of the notes payable? By the subordinated debentures? By the common stockholders?

PROBLEMS

Answers Are in Appendix B

EASY PROBLEM 1

(24-1) Liquidation

Southwestern Wear Inc. has the following balance sheet:

Current assets	$1,875,000	Accounts payable	$ 375,000
Fixed assets	1,875,000	Notes payable	750,000
		Subordinated debentures	750,000
		Total debt	$1,875,000
		Common equity	1,875,000
Total assets	$3,750,000	Total liabilities and equity	$3,750,000

The trustee's costs total $281,250, and the firm has no accrued taxes or wages. The debentures are subordinated only to the notes payable. If the firm goes bankrupt and liquidates, how much will each class of investors receive if a total of $2.5 million is received from sale of the assets?

INTERMEDIATE PROBLEM 2

(24-2) Reorganization

The Verbrugge Publishing Company's 2016 balance sheet and income statement are as follows (in millions of dollars):

Balance Sheet

Balance Sheet			
Current assets	$168	Current liabilities	$ 42
Net fixed assets	153	Advance payments	78
Goodwill	15	Reserves	6
		$6 preferred stock, $112.50 par value (1,200,000 shares)	135
		$10.50 preferred stock, no par, callable at $150 (60,000 shares)	9
		Common stock, $1.50 par value (6,000,000 shares)	9
		Retained earnings	57
Total assets	$336	Total claims	$336

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Income Statement

Net sales	$540.0
Operating expense	516.0
Net operating income	$ 24.0
Other income	3.0
EBT	$ 27.0
Taxes (50%)	13.5
Net income	$ 13.5
Dividends on $6 preferred	7.2
Dividends on $10.50 preferred	0.6
Income available to common stockholders	$ 5.7

Verbrugge and its creditors have agreed upon a voluntary reorganization plan. In this plan, each share of the $6 preferred will be exchanged for one share of $2.40 preferred with a par value of $37.50 plus one 8% subordinated income debenture with a par value of $75. The $10.50 preferred issue will be retired with cash.

a. Construct the projected balance sheet while assuming that reorganization takes place. Show the new preferred stock at its par value.
b. Construct the projected income statement. What is the income available to common shareholders in the proposed recapitalization?
c. *Required earnings* is defined as the amount that is just enough to meet fixed charges (debenture interest and/or preferred dividends). What are the required pre-tax earnings before and after the recapitalization?
d. How is the debt ratio affected by the reorganization? If you were a holder of Verbrugge's common stock, would you vote in favor of the reorganization? Why or why not?

CHALLENGING PROBLEMS 3–4

(24-3) Liquidation

At the time it defaulted on its interest payments and filed for bankruptcy, the McDaniel Mining Company had the balance sheet shown here (in thousands of dollars). The court, after trying unsuccessfully to reorganize the firm, decided that the only recourse was liquidation under Chapter 7. Sale of the fixed assets, which were pledged as collateral to the mortgage bondholders, brought in $400,000, while the current assets were sold for another $200,000. Thus, the total proceeds from the liquidation sale were $600,000. The trustee's costs amounted to $50,000; no single worker was due more than the maximum allowable wages per worker; and there were no unfunded pension plan liabilities.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Current assets	$ 400	Accounts payable	$ 50
Net fixed assets	600	Accrued taxes	40
		Accrued wages	30
		Notes payable	180
		Total current liabilities	$ 300
		First-mortgage bonds[a]	300
		Second-mortgage bonds[a]	200
		Debentures	200
		Subordinated debentures[b]	100
		Common stock	50
		Retained earnings	(150)
Total assets	$1,000	Total claims	$1,000

Notes:

[a]All fixed assets are pledged as collateral to the mortgage bonds.

[b]Subordinated to notes payable only.

a. How much will McDaniel's shareholders receive from the liquidation?
b. How much will the mortgage bondholders receive?
c. Who are the other priority claimants (in addition to the mortgage bondholders)? How much will they receive from the liquidation?
d. Who are the remaining general creditors? How much will each receive from the distribution before subordination adjustment? What is the effect of adjusting for subordination?

(24-4) Liquidation

The following balance sheet represents Boles Electronics Corporation's position at the time it filed for bankruptcy (in thousands of dollars):

Cash	$ 10	Accounts payable	$ 1,600
Receivables	100	Notes payable	500
Inventories	890	Wages payable	150
		Taxes payable	50
Total current assets	$ 1,000	Total current liabilities	$ 2,300
Net plant	4,000	Mortgage bonds	2,000
Net equipment	5,000	Subordinated debentures	2,500
		Preferred stock	1,500
		Common stock	1,700
Total assets	$10,000	Total claims	$10,000

The mortgage bonds are secured by the plant but not by the equipment. The subordinated debentures are subordinated to notes payable. The firm was unable to reorganize under Chapter 11; therefore, it was liquidated under Chapter 7. The trustee, whose legal and administrative fees amounted to $200,000, sold off the assets and received the following proceeds (in thousands of dollars):

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Asset	Proceeds
Plant	$1,600
Equipment	1,300
Receivables	50
Inventories	240
Total	$3,190

In addition, the firm had $10,000 in cash available for distribution. No single wage earner had claims exceeding the maximum allowable wages per worker, and there were no unfunded pension plan liabilities.

a. What is the total amount available for distribution to all claimants? What is the total of creditor and trustee claims? Will the preferred and common stockholders receive any distributions?
b. Determine the dollar distribution to each creditor and to the trustee. What percentage of each claim is satisfied?

SPREADSHEET PROBLEM

(24-5)
Liquidation

Start with the partial model in the file ***Ch24 P05 Build a Model.xlsx*** on the textbook's Web site. Duchon Industries had the following balance sheet at the time it defaulted on its interest payments and filed for liquidation under Chapter 7. Sale of the fixed assets, which were pledged as collateral to the mortgage bondholders, brought in $900 million, while the current assets were sold for another $401 million. Thus, the total proceeds from the liquidation sales were $1,300 million. The trustee's costs amounted to $1 million; no single worker was due more than the maximum allowable wages per worker; and there were no unfunded pension plan liabilities. Determine the amount available for distribution to shareholders and all claimants.

resource

Duchon Industries' Balance Sheets (Millions of Dollars)

Current assets	$ 400	Accounts payable	$ 50
Net fixed assets	600	Accrued taxes	40
		Accrued wages	30
		Notes payable	180
		Total current liabilities	$ 300
		First-mortgage bonds[a]	300
		Second-mortgage bonds[a]	200
		Debentures	200
		Subordinated debentures[b]	100
		Common stock	50
		Retained earnings	(150)
Total assets	$1,000	Total claims	$1,000

Notes:

[a]All fixed assets are pledged as collateral to the mortgage bonds.

[b]Subordinated to notes payable only.

MINI CASE

Kimberly MacKenzie—president of Kim's Clothes Inc., a medium-sized manufacturer of women's casual clothing—is worried. Her firm has been selling clothes to Russ Brothers Department Store for more than 10 years, and she has never experienced any problems in collecting payment for the merchandise sold. Currently, Russ Brothers owes Kim's Clothes $65,000 for spring sportswear that was delivered to the store just 2 weeks ago. Kim's concern arose from reading an article in yesterday's *Wall Street Journal* that indicated Russ Brothers was having serious financial problems. Moreover, the article stated that Russ Brothers' management was considering filing for reorganization, or even liquidation, with a federal bankruptcy court.

Kim's immediate concern is whether her firm will collect its receivables if Russ Brothers goes bankrupt. In pondering the situation, Kim has also realized that she knows nothing about the process that firms go through when they encounter severe financial distress. To learn more about bankruptcy, reorganization, and liquidation, Kim has asked Ron Mitchell, her firm's chief financial officer, to prepare a briefing on the subject for the entire board of directors. In turn, Ron has asked you, a newly hired financial analyst, to do the groundwork for the briefing by answering the following questions.

a. (1) What are the major causes of business failure?
   (2) Do business failures occur evenly over time?
   (3) Which size of firm, large or small, is more prone to business failure? Why?

b. What key issues must managers face in the financial distress process?

c. What informal remedies are available to firms in financial distress? In answering this question, define the following terms:
   (1) Workout
   (2) Restructuring
   (3) Extension
   (4) Composition
   (5) Assignment
   (6) Assignee (trustee)

d. Briefly describe U.S. bankruptcy law, including the following terms:
   (1) Chapter 11
   (2) Chapter 7
   (3) Trustee
   (4) Voluntary bankruptcy
   (5) Involuntary bankruptcy

e. What are the major differences between an informal reorganization and reorganization in bankruptcy? In answering this question, be sure to discuss the following items:
   (1) Common pool problem
   (2) Holdout problem
   (3) Automatic stay
   (4) Cramdown
   (5) Fraudulent conveyance

f. What is a prepackaged bankruptcy? Why have prepackaged bankruptcies become more popular in recent years?

g. Briefly describe the priority of claims in a Chapter 7 liquidation.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

h. Assume that Russ Brothers did indeed fail, and that it had the following balance sheet when it was liquidated (in millions of dollars):

Current assets	$40.0	Accounts payable	$10.0
Net fixed assets	5.0	Notes payable (to banks)	5.0
		Accrued wages	0.3
		Federal taxes	0.5
		State and local taxes	0.2
		Current liabilities	$16.0
		First-mortgage bonds	3.0
		Second-mortgage bonds	0.5
		Subordinated debentures[a]	4.0
		Total long-term debt	$ 7.5
		Preferred stock	1.0
		Common stock	13.0
		Paid-in capital	2.0
		Retained earnings	5.5
		Total equity	$21.5
Total assets	$45.0	Total claims	$45.0

Note:

[a]The debentures are subordinated to the notes payable.

The liquidation sale resulted in the following proceeds:

From sale of current assets	$14,000,000
From sale of fixed assets	2,500,000
Total receipts	$16,500,000

For simplicity, assume there were no trustee's fees or any other claims against the liquidation proceeds. Also, assume that the mortgage bonds are secured by the entire amount of fixed assets. What would each claimant receive from the liquidation distribution?

SELECTED ADDITIONAL CASES

The following case from CengageCompose covers many of the concepts discussed in this chapter and is available at **http://compose.cengage.com.**

Klein-Brigham Series:
Case 39, "Mark X Company (B)," which examines the allocation of proceeds under bankruptcy.

CHAPTER 25

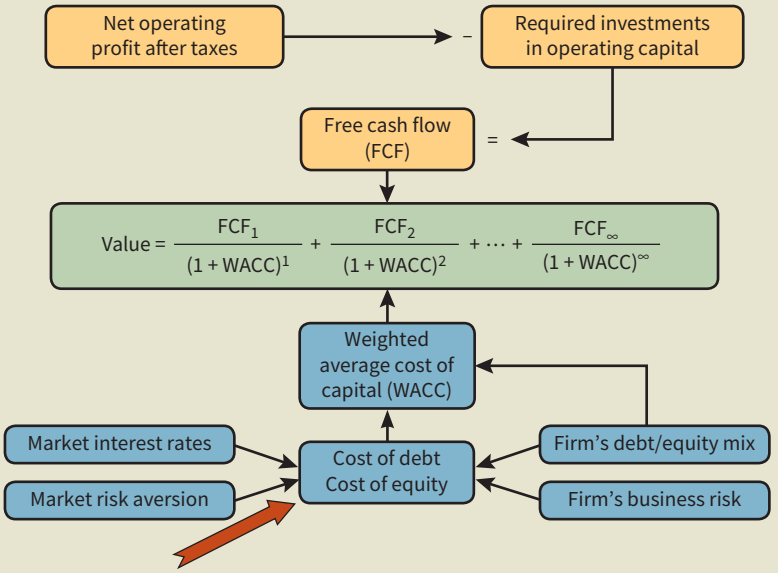
Portfolio Theory and Asset Pricing Models

Americans love mutual funds. By 1985, they had invested about $495 billion in mutual funds, which is not exactly chicken feed. By December 2014, however, they had invested more than $12.03 trillion in mutual funds! Not only has the amount of money invested in mutual funds skyrocketed, but the variety of funds is astounding. You can buy funds that specialize in virtually any type of asset: funds that specialize in stocks from a particular industry, a particular continent, or a particular country. There are money market funds that invest only in Treasury bills and other short-term securities, and there are even funds that hold municipal bonds from a specific state.

For those with a social conscience, there are funds that refuse to own stocks of companies that pollute, sell tobacco products, or have workforces that are not culturally diverse. For others, there are "vice" funds, which invest only in brewers, defense contractors, tobacco companies, and the like.

You can buy an index fund, which simply holds a portfolio of stocks in an index such as the S&P 500. Index funds don't try to beat the market. Instead, they try to keep their expenses low and pass the savings on to investors. An exchange-traded fund, or ETF, has its own stock that is traded on a stock exchange. Different ETFs hold widely varied portfolios, ranging from the S&P 500 to gold-mining companies to Middle Eastern oil companies, and their fees to long-term investors are quite low. At the other extreme, hedge funds, which are pools of money provided by institutions and wealthy individuals, are very actively managed—even to the extent of taking over and then operationally managing firms in the portfolio—and they have relatively high expenses.



As you read this chapter, think about how portfolio theory, which became widely understood about 30 years ago, has influenced the mutual fund industry.

Sources: The Investment Company Institute publishes a *Fact Book* containing updated information on mutual funds. See **www.ici.org/research/stats/factbook.**

Intrinsic Value, Risk, and Return

In Chapter 1, we told you that managers should strive to make their firms more valuable and that the value of a firm is determined by the size, timing, and risk of its free cash flows (FCF). In Chapter 6, we discussed risk, which affects WACC and value. Now we provide additional insights into how to manage a portfolio's risk and measure a firm's risk.

resource

The textbook's Web site contains an Excel *file that will guide you through the chapter's calculations. The file for this chapter is* ***Ch25 Tool Kit.xlsx****, and we encourage you to open the file and follow along as you read the chapter.*

In Chapter 6, we presented the key elements of risk and return analysis. There we saw that much of a stock's risk can be eliminated by diversification, so rational investors should hold portfolios of stocks rather than shares of a single stock. We also introduced the Capital Asset Pricing Model (CAPM), which links risk and required rates of return and uses a stock's beta coefficient as the relevant measure of risk. In this chapter, we extend these concepts and explain portfolio theory. We then present an in-depth treatment of the CAPM, including a more detailed look at how betas are calculated. We also describe the Arbitrage Pricing Theory model.

25-1 Efficient Portfolios

Recall from Chapter 6 the important role in portfolio risk that is played by the correlation between assets. One important use of portfolio risk concepts is to select **efficient portfolios**, defined as those portfolios that provide the highest expected return for any specified level of risk—or the lowest degree of risk for any specified level of return. We begin with the two-asset case and then extend it to the general case of N assets.

25-1a The Two-Asset Case

Consider two assets, A and B. Suppose we have estimated the expected returns ($\hat{r}_A$ and $\hat{r}_B$), the standard deviations (σ_A and σ_B) of returns, and the correlation coefficient (ρ_{AB})

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. for returns.[1] The expected return and standard deviation (SD) for a portfolio containing these two assets are:

$$\hat{r}_p = w_A\hat{r}_A + (1 - w_A)\hat{r}_B \quad (25\text{-}1)$$

and

$$\text{Portfolio SD} = \sigma_p = \sqrt{w_A^2\sigma_A^2 + (1 - w_A)^2\sigma_B^2 + 2w_A(1 - w_A)\rho_{AB}\sigma_A\sigma_B} \quad (25\text{-}2)$$

Here w_A is the fraction of the portfolio invested in Security A, so $(1 - w_A)$ is the fraction invested in Security B.

To illustrate, suppose we can allocate our funds between A and B in any proportion. Suppose Security A has an expected rate of return of $\hat{r}_A = 5\%$ and a standard deviation of returns of $\sigma_A = 4\%$, while $\hat{r}_B = 8\%$ and $\sigma_B = 10\%$. Our first task is to determine the set of **feasible portfolios**, which are the ones that are *attainable* given the risk and expected return of Securities A and B. The second step is to examine the **attainable portfolios** and select the *efficient* subset.

To construct the attainable set, we need data on the degree of correlation between the two securities' expected returns, ρ_{AB}. Let us work with three different assumed degrees of correlation—namely, $\rho_{AB} = +1.0$, $\rho_{AB} = 0$, and $\rho_{AB} = -1.0$—and use them to develop the portfolios' expected returns, $\hat{r}_p$, and standard deviations, σ_p. (Of course, only one correlation can exist; our example simply shows three alternative situations that could occur.)

To calculate $\hat{r}_p$, we use Equation 25-1: Substitute the given values for $\hat{r}_A$ and $\hat{r}_B$, and then calculate $\hat{r}_p$ for different values of w_A. For example, if $w_A = 0.75$, then $\hat{r}_p = 5.75\%$:

$$\begin{aligned}\hat{r}_p &= w_A\hat{r}_A + (1 - w_A)\hat{r}_B \\ &= 0.75(5\%) + 0.25(8\%) = 5.75\%\end{aligned}$$

Other values of $\hat{r}_p$ are found similarly and are shown in the third column of Figure 25-1.

resource

*See **Ch25 Tool Kit.xlsx** on the textbook's Web site for all calculations.*

Next, we use Equation 25-2 to find σ_p. Substitute the given values for σ_A, σ_B, and ρ_{AB}, and then calculate σ_p for different values of w_A. For example, if $\rho_{AB} = 0$ and $w_A = 0.75$, then $\sigma_p = 3.9\%$:

$$\begin{aligned}\sigma_p &= \sqrt{w_A^2\sigma_A^2 + (1 - w_A)^2\sigma_B^2 + 2w_A(1 - w_A)\rho_{AB}\sigma_A\sigma_B} \\ &= \sqrt{(0.75^2)(0.04^2) + (1 - 0.75)^2(0.10^2) + 2(0.75)(1 - 0.75)(0)(0.04)(0.10)} \\ &= \sqrt{0.0009 + 0.000625 + 0} = \sqrt{0.001525} = 0.039 = 3.9\%\end{aligned}$$

Figure 25-1 gives $\hat{r}_p$ and σ_p values for several different value of w_A; Figure 25-2 plots $\hat{r}_p$ and σ_p for each set of weights and correlations. For any given set of weights, the graphs show the feasible set of portfolios. Note the following points:

1. Panel A shows the feasible expected portfolio returns for three different values of correlation: (1) Case 1, with $\rho_{AB} = +1$; (2) Case 2, with $\rho_{AB} = 0$; and (3) Case 3, with $\rho_{AB} = -1$. Notice that these graphs are identical for each of the three cases: The

portfolio return, $\hat{r}_p$, is a linear function of w_A, and it does not depend on the correlation coefficients. This is also seen from the $\hat{r}_p$ column in Figure 25-1. This should not be surprising, because Equation 25-1 shows that a portfolio's expected return is a weighted average of the individual expected returns.

2. Panel B shows how risk is affected by the asset mix in the portfolio. For Case 1, where $\rho_{AB} = +1$, portfolio risk (σ_p) changes linearly as the portfolio weights change. In other words, portfolio risk is a weighted average of the individual standard deviations. However, the graphs for Cases 2 and 3 paint a very different picture. Portfolio risk is a nonlinear function of the weights, with the risk for these cases being lower than the risk for Case 1. This shows that if the stocks are not perfectly positively correlated (i.e., $\rho_{AB} \neq +1$), then combining stocks in a portfolio can diversify away some of its risk. In fact, if $\rho_{AB} = -1$, then risk can be completely diversified away! Thus, a portfolio's risk (σ_p), unlike a portfolio's expected return ($\hat{r}_p$), *does* depend on correlation.
3. Panel C has graphs plotting a portfolio's expected return versus its risk. Unlike the other Panels, which plotted return and risk versus the portfolio's composition, each of these three graphs in Panel C is plotted from pairs of $\hat{r}_p$ and σ_p. For example, Point A (in the first graph of Panel C) is the point $\hat{r}_p = 5\%$ and $\sigma_p = 4\%$, corresponding to $w_A = 100\%$ from Panels A and B for Case 1 (i.e., $\rho_{AB} = +1$). Notice that the relationship between risk and return is linear for Case 1, but not for Cases 2 and 3 in which correlation is not equal to $+1$.
4. Are all portfolios in the feasible set equally good? The answer is "no." Only that part of the feasible set from Y to B in Cases 2 and 3 is defined as *efficient*. The part from A to Y is inefficient because, for any degree of risk on the line segment AY, a higher return can be found on segment YB. Thus, no rational investor would hold a portfolio that lies on segment AY. In Case 1, however, the entire feasible set is efficient—no combination of the securities can be ruled out.
5. We rarely encounter $\rho_{AB} = -1.0, 0.0$, or $+1.0$. Generally, ρ_{AB} is in the range of $+0.3$ to $+0.6$ for most stocks. Case 2 (zero correlation) produces graphs that, pictorially, most closely resemble real-world examples.

From these examples we see that in one extreme case ($\rho = -1.0$), risk can be diversified away completely, while in the other extreme case ($\rho = +1.0$), higher expected returns always

FIGURE 25-2
Illustrations of Portfolio Returns, Risk, and the Feasible Set of Portfolios

have higher risk. In between these extremes, combining two stocks into a portfolio reduces but does not eliminate the risk inherent in the individual stocks.

Panel C of Figure 25-2 shows that there exists a minimum possible risk portfolio (Y) for Cases 2 and 3 (i.e., for $\rho \neq +1.0$). How can we determine the weights for the minimum risk portfolio? Differentiate Equation 25-2 with respect to w_A, set the derivative equal to zero, and then solve for w_A. This identifies the fraction of the portfolio that should be invested in Security A if we wish to form the least-risky portfolio. Here is the equation:

$$\text{Minimum risk portfolio: } w_A = \frac{\sigma_B(\sigma_B - \rho_{AB}\sigma_A)}{\sigma_A^2 + \sigma_B^2 - 2\rho_{AB}\sigma_A\sigma_B} \tag{25-3}$$

A value of w_A that is negative means that Security A is sold short; if w_A is greater than 1, B is sold short. In a short sale, you borrow shares of stock from a broker and then sell them, expecting to buy shares of stock back later (at a lower price) in order to repay the person from whom you borrowed the stock. If you sell short and the stock price rises, then you lose, but you win if the price declines. If the stock pays a dividend, you must pay the

dividend to the broker, who passes it on to the client who provided the shares. Therefore, selling a share short is like owning a negative share of stock.

To find the minimum risk portfolio if short sales are not used, limit w_A to the range 0 to +1.0; that is, if the solution value is $w_A > 1.0$, set w_A to 1.0, and if w_A is negative, set w_A to 0.0.

25-1b The N-Asset Case

The same principles from the two-asset case also apply when the portfolio is composed of N assets. Here is the notation for the N-asset case: The percentage of the investment in asset i (the portfolio weight) is w_i, the expected return for asset i is $\hat{r}_i$, the standard deviation of asset i is σ_i, and the correlation between asset i and asset j is ρ_{ij}. The expected return for a portfolio with N assets is then:

$$\hat{r}_p = \sum_{i=1}^{N} w_i \hat{r}_i \qquad (25\text{-}4)$$

And the variance of the portfolio is:

$$\sigma_p^2 = \sum_{i=1}^{N} \sum_{j=1}^{N} w_i w_j \sigma_i \sigma_j \rho_{ij} \qquad (25\text{-}5)$$

For the case in which i = j, the correlation is $\rho_{ij} = \rho_{ii} = 1$. Notice also that when i = j, the product $\sigma_i \sigma_j = \sigma_i \sigma_i = \sigma_i^2$.

One way to apply Equation 25-5 is to set up a table with a row and column for each asset. Give the rows and columns labels showing the assets' weights and standard deviations. Then fill in each cell in the table by multiplying the values in the row and column headings by the correlation between the assets, as shown here:

	$w_1\sigma_1$ (1)	$w_2\sigma_2$ (2)	$w_3\sigma_3$ (3)
$w_1\sigma_1$ (1)	$w_1\sigma_1 w_1\sigma_1\rho_{11} = w_1^2\sigma_1^2$	$w_1\sigma_1 w_2\sigma_2\rho_{12}$	$w_1\sigma_1 w_3\sigma_3\rho_{13}$
$w_2\sigma_2$ (2)	$w_2\sigma_2 w_1\sigma_1\rho_{21}$	$w_2\sigma_2 w_2\sigma_2\rho_{22} = w_2^2\sigma_2^2$	$w_2\sigma_2 w_3\sigma_3\rho_{23}$
$w_3\sigma_3$ (3)	$w_3\sigma_3 w_1\sigma_1\rho_{31}$	$w_3\sigma_3 w_2\sigma_2\rho_{32}$	$w_3\sigma_3 w_3\sigma_3\rho_{33} = w_3^2\sigma_3^2$

The portfolio variance is the sum of the nine cells. For the diagonal, we have substituted the values for the case in which i = j. Notice that some of the cells have identical values. For example, the cell for Row 1 and Column 2 has the same value as the cell for Column 1 and Row 2. This suggests an alternative formula:

$$\sigma_p^2 = \sum_{i=1}^{N} w_i^2 \sigma_i^2 + \sum_{i=1}^{N} \sum_{\substack{j=1 \\ j \neq i}}^{N} w_i \sigma_i w_j \sigma_j \rho_{ij} \qquad (25\text{-}5a)$$

The main thing to remember when calculating portfolio standard deviations is simply this: Do not leave out any terms. Using a table like the one shown here can help.

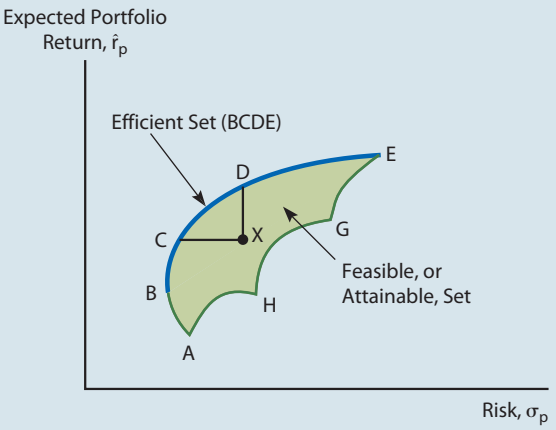
SELF-TEST

What does the term "attainable set" mean?

Within the attainable set, which portfolios are "efficient"?

Stock A has an expected return of 10% and a standard deviation of 35%. Stock B has an expected return of 15% and a standard deviation of 45%. The correlation coefficient between Stocks A and B is 0.3. What are the expected return and standard deviation of a portfolio invested 60% in Stock A and 40% in Stock B? **(12.0%; 31.5%)**

25-2 Choosing the Optimal Portfolio



With only two assets, the feasible set of portfolios is a line or curve, as shown in Figure 25-2, Panel C. However, by increasing the number of assets, we obtain an area, such as the shaded region in Figure 25-3. Points A, H, G, and E represent single securities (or portfolios containing only one security). All the other points in the shaded area and its boundaries, which comprise the feasible set, represent portfolios of two or more securities. Each point in this area represents a particular portfolio with a risk of σ_p and an expected return of $\hat{r}_p$. For example, Point X represents one such portfolio's risk and expected return, as do each of Points B, C, and D.

Given the full set of potential portfolios that could be constructed from the available assets, which portfolio should actually be held? This choice involves two separate decisions: (1) determining the efficient set of portfolios and (2) choosing from the efficient set the single portfolio that is best for the specific investor.

25-2a The Efficient Frontier

In Figure 25-3, the boundary line BCDE defines the efficient set of portfolios, which is also called the **efficient frontier**.[2] Portfolios to the left of the efficient set are not possible

FIGURE 25-3
The Efficient Set of Investments

[2]A computational procedure for determining the efficient set of portfolios was developed by Harry Markowitz and first reported in his article "Portfolio Selection," *Journal of Finance*, March 1952, pp. 77–91. In this article, Markowitz developed the basic concepts of portfolio theory, and he later won the Nobel Prize in economics for his work.

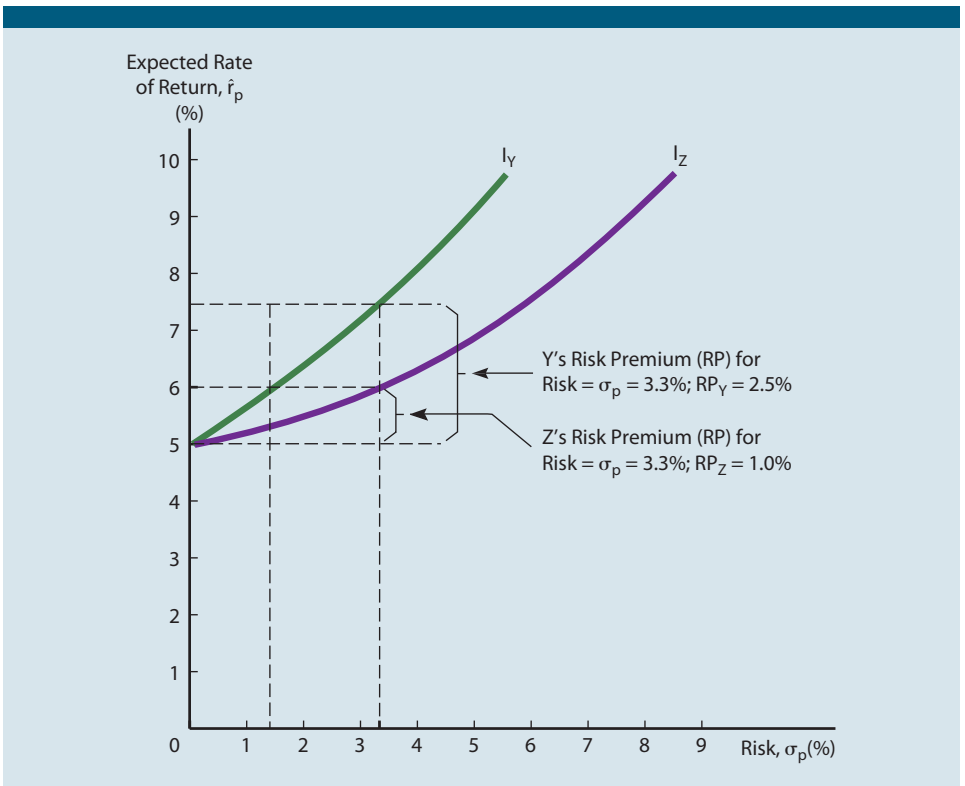
because they lie outside the attainable set. Portfolios to the right of the boundary line (interior portfolios) are inefficient because some other portfolio would provide either a higher return for the same degree of risk or a lower risk for the same rate of return. For example, Portfolio X is *dominated* in this sense by all portfolios on the curve CD.



25-2b Risk–Return Indifference Curves

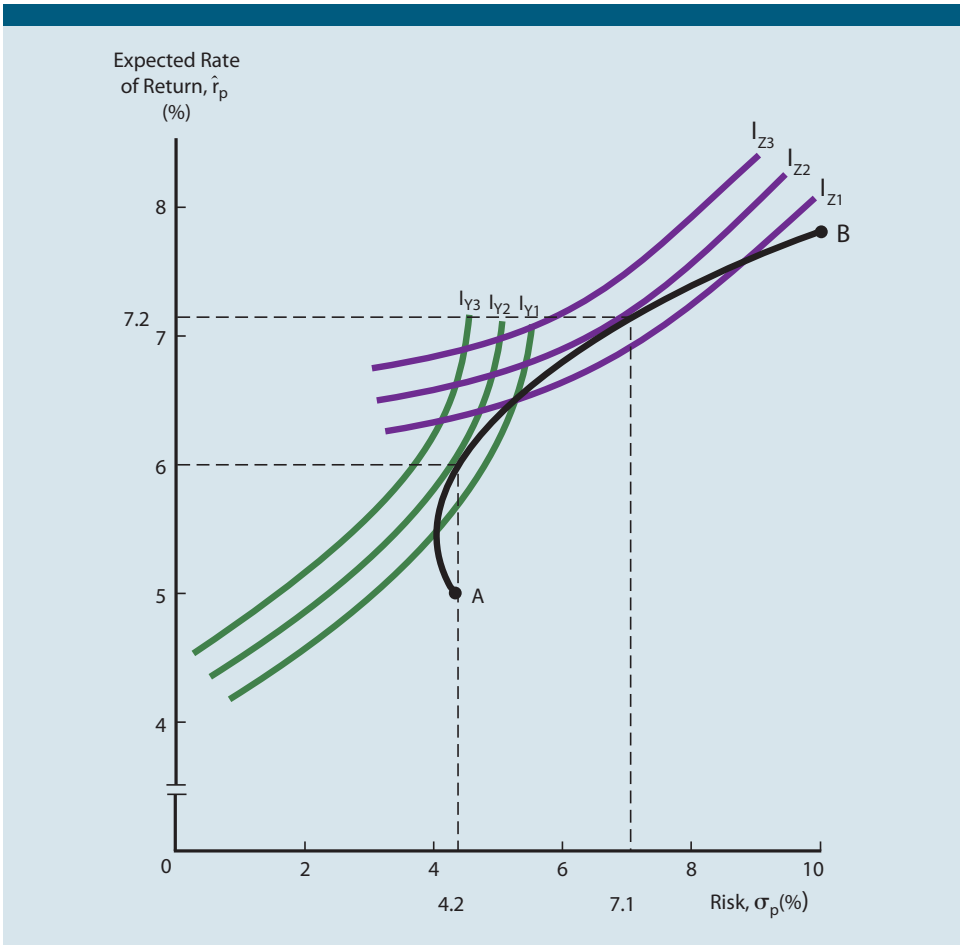
Given the efficient set of portfolios, which specific portfolio should an investor choose? To determine the optimal portfolio for a particular investor, we must know the investor's attitude toward risk as reflected in his or her risk–return trade-off function, or **indifference curve**.

An investor's risk–return trade-off function is based on the standard economic concepts of utility theory and indifference curves, which are illustrated in Figure 25-4. The curves labeled I_Y and I_Z represent the indifference curves of two individuals, Ms. Y and Mr. Z. Ms. Y's curve indicates indifference between the riskless 5% portfolio, a portfolio with an expected return of 6% but a risk of $\sigma_p = 1.4\%$, and so on. Mr. Z's curve indicates indifference between a riskless 5% return, an expected 6% return with risk of $\sigma_p = 3.3\%$, and so on.

Note that Ms. Y requires a higher expected rate of return as compensation for any given amount of risk; thus, Ms. Y is said to have more **risk aversion** than Mr. Z. Her higher risk aversion causes Ms. Y to require a higher **risk premium**—defined here as the difference between the 5% riskless return and the expected return required to compensate for any

FIGURE 25-4
Risk–Return Indifference Curves

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.



specific amount of risk—than Mr. Z requires. Thus, Ms. Y requires a risk premium (RP_Y) of 2.5% to compensate for a risk of $\sigma_p = 3.3\%$, whereas Mr. Z's risk premium for this degree of risk is only $RP_Z = 1.0\%$. *In general, an indifference curve with a steeper slope means that the investor is more risk averse.* Thus, Ms. Y is more risk averse than Mr. Z.

Each individual has a "map" of indifference curves; the indifference maps for Ms. Y and Mr. Z are shown in Figure 25-5. The higher curves denote a greater level of satisfaction (or utility). Thus, I_{Z2} is better than I_{Z1} because, for any level of risk, Mr. Z has a higher expected return and hence greater utility. An infinite number of indifference curves could be drawn in the map for each individual, and each individual has a unique map.

25-2c The Optimal Portfolio for an Investor

Figure 25-5 also shows the feasible set of portfolios for the two-asset case, under the assumption that $\rho_{AB} = 0$, as it was developed in Figure 25-2. The **optimal portfolio** for each investor is found at the tangency point between the efficient set of portfolios and one of the investor's indifference curves. This tangency point marks the highest level of

FIGURE 25-5

satisfaction the investor can attain. Ms. Y, who is more risk averse than Mr. Z, chooses a portfolio with a lower expected return (about 6%) but a risk of only $\sigma_p = 4.2\%$. Mr. Z picks a portfolio that provides an expected return of about 7.2% but has a risk of about $\sigma_p = 7.1\%$. Ms. Y's portfolio is more heavily weighted with the less risky security, while Mr. Z's portfolio contains a larger proportion of the more risky security.[3]

SELF-TEST

What is the efficient frontier?

What are indifference curves?

Conceptually, how does an investor choose his or her optimal portfolio?

25-3 The Basic Assumptions of the Capital Asset Pricing Model

The **Capital Asset Pricing Model (CAPM)**, which was introduced in Chapter 6, specifies the relationship between risk and required rates of return on assets when they are held in well-diversified portfolios. The assumptions underlying the CAPM's development are summarized in the following list.[4]

1. All investors focus on a single holding period, and they seek to maximize the expected utility of their terminal wealth by choosing among alternative portfolios on the basis of each portfolio's expected return and standard deviation.
2. All investors can borrow or lend an unlimited amount at a given risk-free rate of interest, r_{RF}, and there are no restrictions on short sales of any asset.
3. All investors have identical estimates of the expected returns, variances, and covariances among all assets (that is, investors have homogeneous expectations).
4. All assets are perfectly divisible and perfectly liquid (that is, marketable at the going price).
5. There are no transaction costs.
6. There are no taxes.
7. All investors are price takers (that is, all investors assume that their own buying and selling activity will not affect stock prices).
8. The quantities of all assets are given and fixed.

Theoretical extensions in the literature have relaxed some of these assumptions, and, in general, these extensions have led to conclusions that are reasonably consistent with the basic theory. However, the validity of any model can be established only through empirical tests, which we discuss later in the chapter.

SELF-TEST

What are the key assumptions of the CAPM?

[3]Ms. Y's portfolio would contain 67% of Security A and 33% of Security B, whereas Mr. Z's portfolio would consist of 27% of Security A and 73% of Security B. These percentages can be determined with Equation 25-1 by simply seeing what percentage of the two securities is consistent with $\hat{r}_p = 6.0\%$ and 7.2%. For example, $w_A(5\%) + (1 - w_A)(8\%) = 7.2\%$, and solving for w_A, we obtain $w_A = 0.27$ and $(1 - w_A) = 0.73$.

[4]The CAPM was originated by William F. Sharpe in his article "Capital Asset Prices: A Theory of Market Equilibrium under Conditions of Risk," *Journal of Finance*, September 1964, pp. 425–442. Professor Sharpe won the Nobel Prize in economics for his work on capital asset pricing. The assumptions inherent in Sharpe's model were spelled out by Michael C. Jensen in "Capital Markets: Theory and Evidence," *Bell Journal of Economics and Management Science*, Autumn 1972, pp. 357–398.

25-4 The Capital Market Line and the Security Market Line

Figure 25-5 showed the set of portfolio opportunities for the two-asset case, and it illustrated how indifference curves can be used to select the optimal portfolio from the feasible set. In Figure 25-6, we show a similar diagram for the many-asset case, but here we also include a risk-free asset with a return r_{RF}. The riskless asset by definition has zero risk, $\sigma = 0\%$, so it is plotted on the vertical axis.

The figure shows both the feasible set of portfolios of risky assets (the shaded area) and a set of indifference curves (I_1, I_2, I_3) for a particular investor. Point N, where indifference curve I_1 is tangent to the efficient set, represents a possible portfolio choice; it is the point on the efficient set of risky portfolios where the investor obtains the highest possible return for a given amount of risk and the smallest degree of risk for a given expected return.

However, the investor can do better than Portfolio N by reaching a higher indifference curve. In addition to the feasible set of risky portfolios, we now have a risk-free asset that provides a riskless return, r_{RF}. Given the risk-free asset, investors can create new portfolios that combine the risk-free asset with a portfolio of risky assets. This enables them to achieve any combination of risk and return on the straight line connecting r_{RF} with M, the point of tangency between that straight line and the efficient frontier of risky asset

FIGURE 25-6
Investor Equilibrium: Combining the Risk-Free Asset with the Market Portfolio

portfolios.[5] Some portfolios on the line $r_{RF}MZ$ will be preferred to most risky portfolios on the efficient frontier BNME, so the points on the line $r_{RF}MZ$ now represent the best attainable combinations of risk and return.

Given the new opportunities along line $r_{RF}MZ$, our investor will move from Point N to Point R, which is on her highest attainable risk–return indifference curve. Note that any point on the old efficient frontier BNME (except the point of tangency M) is dominated by some point along the line $r_{RF}MZ$. In general, because investors can purchase some of the risk-free security and some of the risky portfolio (M), it will be possible to move to a point such as R. In addition, if the investor can borrow as well as lend (lending is equivalent to buying risk-free debt securities) at the riskless rate r_{RF}, then it is possible to move out on the line segment MZ; an investor would do so if his or her indifference curve were tangent to $r_{RF}MZ$, to the right of Point M.[6]

All investors should hold portfolios lying on the line $r_{RF}MZ$ under the conditions assumed in the CAPM. This implies that they should hold portfolios that are combinations of the risk-free security and the risky Portfolio M. Thus, the addition of the risk-free asset totally changes the efficient set: The efficient set now lies along line $r_{RF}MZ$ rather

[5]The risk–return combinations between a risk-free asset and a risky asset (a single stock or a portfolio of stocks) will always be linear. To see this, consider the following equations, which were developed earlier, for return ($\hat{r}_p$) and risk (σ_p) for any combination w_{RF} and $(1 - w_{RF})$:

$$\hat{r}_p = w_{RF} r_{RF} + (1 - w_{RF})\hat{r}_M \quad \textbf{(25-1a)}$$

and

$$\sigma_P = \sqrt{w_{RF}^2\sigma_{RF}^2 + (1 - w_{RF})^2\sigma_M^2 + 2w_{RF}(1 - w_{RF})\rho_{RF,M}\sigma_{RF}\sigma_M} \quad \textbf{(25-2a)}$$

Equation 25-1a is linear. As for Equation 25-2a, we know that r_{RF} is the risk-free asset, so $\sigma_{RF} = 0$; hence, σ_{RF}^2 is also zero. Using this information, we can simplify Equation 25-2a as follows:

$$\sigma_p = \sqrt{(1 - w_{RF})^2\sigma_M^2} = (1 - w_{RF})\sigma_M \quad \textbf{(25-2b)}$$

Thus, σ_p is also linear when a riskless asset is combined with a portfolio of risky assets.

If expected returns, as measured by $\hat{r}_p$, and risk, as measured by σ_p, are both linear functions of w_{RF}, then the relationship between $\hat{r}_p$ and σ_p, when graphed as in Figure 25-6, must also be linear. For example, if 100% of the portfolio is invested in r_{RF} with a return of 8%, then the portfolio return will be 8% and σ_p will be 0. If 100% is invested in M with $r_M = 12\%$ and $\sigma_M = 10\%$, then $\sigma_p = 1.0(10\%) = 10\%$ and $\hat{r}_p = 0(8\%) + 1.0(12\%) = 12\%$. If 50% of the portfolio is invested in M and 50% in the risk-free asset, then $\sigma_p = 0.5(10\%) = 5\%$ and $\hat{r}_p = 0.5(8\%) + 0.5(12\%) = 10\%$. Plotting these points will reveal the linear relationship given as $r_{RF}MZ$ in Figure 25-6.

[6]An investor who is highly risk averse will have a steep indifference curve and will end up holding only the riskless asset or perhaps a portfolio at a point such as R (i.e., holding some of the risky market portfolio and some of the riskless asset). An investor who is only slightly averse to risk will have a relatively flat indifference curve, which will cause her to move out beyond M toward Z, borrowing to do so. This investor might buy stocks on margin, which means borrowing and using the stocks as collateral. If individuals' borrowing rates are higher than r_{RF}, then the line $r_{RF}MZ$ will tilt down (i.e., be less steep) beyond M. This condition would invalidate the basic CAPM, or at least require it to be modified. Therefore, the assumption of being able to borrow or lend at the same rate is crucial to CAPM theory.

than along the curve BNME. Note also that if the capital market is to be in equilibrium, then M must be a portfolio that contains every risky asset in exact proportion to that asset's fraction of the total market value of all assets. In other words, if Security i is X percent of the total market value of all securities, then X percent of the market portfolio M must consist of Security i. (That is, M is the market value–weighted portfolio of *all* risky assets in the economy.) Thus, all investors should hold portfolios that lie on the line $r_{RF}MZ$, with the particular location of a given individual's portfolio being determined by the point at which his indifference curve is tangent to the line.

The line $r_{RF}MZ$ in Figure 25-6 is called the **Capital Market Line (CML)**. It has an intercept of r_{RF} and a slope of $(\hat{r}_M - r_{RF})/\sigma_M$.[7] The equation for the Capital Market Line may be expressed as follows:

$$\text{CML: } \hat{r}_p = r_{RF} + \left(\frac{\hat{r}_M - r_{RF}}{\sigma_M}\right)\sigma_p \qquad (25\text{-}6)$$

The expected rate of return *on an efficient portfolio* is equal to the riskless rate plus a risk premium that is equal to $(\hat{r}_M - r_{RF})/\sigma_M$ multiplied by the portfolio's standard deviation, σ_p. Thus, the CML specifies a linear relationship between an efficient portfolio's expected return and risk, where the slope of the CML is equal to the expected return on the market portfolio of risky stocks $(\hat{r}_M)$ *minus* the risk-free rate (r_{RF}), which is called the **market risk premium**, all divided by the standard deviation of returns on the market portfolio, σ_M:

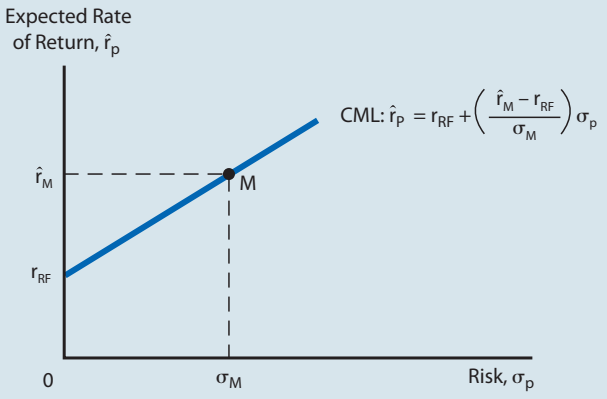
$$\text{Slope of the CML} = (\hat{r}_M - r_{RF})/\sigma_M$$

For example, suppose $r_{RF} = 10\%$, $\hat{r}_M = 15\%$, and $\sigma_M = 15\%$. In this case, the slope of the CML would be $(15\% - 10\%)/15\% = 0.33$, and if a particular efficient portfolio had $\sigma_p = 10\%$, then its $\hat{r}_p$ would be:

$$\hat{r}_p = 10\% + 0.33(10\%) = 13.3\%$$

A (riskier) portfolio with $\sigma_p = 20\%$ would have $\hat{r}_p = 10\% + 0.33(20\%) = 16.6\%$.

The CML is graphed in Figure 25-7. It is a straight line with an intercept at r_{RF} and a slope equal to the market risk premium $(r_M - r_{RF})$ divided by σ_M. The slope of the CML reflects the aggregate attitude of investors toward risk.



Recall that an efficient portfolio is well diversified; hence, all of its unsystematic risk has been eliminated and its only remaining risk is market risk. Therefore, unlike individual stocks, the risk of an efficient portfolio is measured by its standard deviation, σ_p. The CML equation specifies the relationship between risk and return for such efficient portfolios—that is, for portfolios that lie on the CML—and in the CML equation and graph risk is measured by portfolio standard deviation.

The CML specifies the relationship between risk and return for an efficient portfolio, but investors and managers are more concerned about the relationship between risk and return for *individual assets*. To develop the risk–return relationship for individual securities, note in Figure 25-6 that all investors are assumed to hold Portfolio M, so M must be the market portfolio (i.e., the one that contains all stocks). Note also that M is an *efficient* portfolio. Thus, the CML defines the relationship between the market portfolio's expected

[7] Recall that the slope of any line is measured as $\Delta Y/\Delta X$, or the change in height associated with a given change in horizontal distance. Here, r_{RF} is at 0 on the horizontal axis, so $\Delta X = \sigma_M - 0 = \sigma_M$. The vertical axis difference associated with a change from r_{RF} to $\hat{r}_M$ is $\hat{r}_M - r_{RF}$. Therefore, slope $= \Delta Y/\Delta X = (\hat{r}_M - r_{RF})/\sigma_M$.

FIGURE 25-7
The Capital Market Line (CML)

Note: We did not draw it in, but you can visualize the shaded space shown in Figure 25-6 in this graph and the CML as the line formed by connecting r_{RF} with the tangent to the shaded space.

return and its standard deviation. Equations 25-4 and 25-5 show the formulas for the expected return and standard deviation for a multi-asset portfolio, including the market portfolio. It is possible to take the equations for the expected return and standard deviation of a multi-asset portfolio and show that the required return for each individual Stock i must conform to the following equation in order for the CML to hold for the market portfolio:[8]

$$r_i = r_{RF} + \frac{(r_M - r_{RF})}{\sigma_M}\left(\frac{Cov(r_i, r_M)}{\sigma_M}\right)$$
$$= r_{RF} + (r_M - r_{RF})\left(\frac{Cov(r_i, r_M)}{\sigma_M^2}\right) \quad (25\text{-}7)$$

The CAPM defines Company i's beta coefficient, b_i, as follows:

$$b_i = \frac{\text{Covariance between Stock i and the market}}{\text{Variance of market returns}} = \frac{Cov(r_i, r_M)}{\sigma_M^2}$$
$$= \frac{\rho_{iM}\sigma_i\sigma_M}{\sigma_M^2} = \rho_{iM}\left(\frac{\sigma_i}{\sigma_M}\right) \quad (25\text{-}8)$$

[8]For consistency with most investment textbooks, we let $Cov(r_i,r_M)$ denote the covariance between the returns of assets i and M. Using the notation in Chapter 6, we would have denoted the covariance as $COV_{i,M}$.

Recall that the risk premium for the market, RP_M, is $r_M - r_{RF}$. Using this definition and substituting Equation 25-8 into Equation 25-7 gives the **Security Market Line (SML)**:

$$\begin{aligned} \text{SML: } r_i &= r_{RF} + (r_M - r_{RF})b_i \\ &= r_{RF} + (RP_M)b_i \end{aligned} \tag{25-9}$$

The SML tells us that an individual stock's required return is equal to the risk-free rate plus a premium for bearing risk. The premium for risk is equal to the risk premium for the market, RP_M, multiplied by the risk of the individual stock, as measured by its beta coefficient. The beta coefficient measures the amount of risk that the stock contributes to the market portfolio.

Unlike the CML for a well-diversified portfolio, the SML tells us that the standard deviation (σ_i) of an individual stock should not be used to measure its risk, because some of the risk as reflected by σ_i can be eliminated by diversification. Beta reflects risk after taking diversification benefits into account, and so beta, rather than σ_i, is used to measure individual stocks' risks to investors. Be sure to keep in mind the distinction between the SML and the CML and why that distinction exists.

SELF-TEST

Draw a graph showing the feasible set of risky assets, the efficient frontier, the risk-free asset, and the CML.

Write out the equation for the CML and explain its meaning.

Write out the equation for the SML and explain its meaning.

What is the difference between the CML and the SML?

The standard deviation of stock returns of Park Corporation is 60%. The standard deviation of the market return is 20%. If the correlation between Park and the market is 0.40, what is Park's beta? **(1.2)**

25-5 Calculating Beta Coefficients

Equation 25-8 defines beta, but recall from Chapter 6 that this equation for beta is also the formula for the slope coefficient in a regression of the stock return against the market return. Therefore, beta can be calculated by plotting the historical returns of a stock on the y-axis of a graph versus the historical returns of the market portfolio on the x-axis and then fitting the regression line. In his 1964 article that set forth the CAPM, Sharpe called this regression line the **characteristic line**. Thus, a stock's beta is the slope of its characteristic line.

In Chapter 6, we estimated General Electric's beta using 4 years of monthly returns. In this chapter, we estimate betas using 1 year of weekly returns because this is another often-used approach. In addition to estimating the beta of a company in this chapter (Apple), we also estimate the beta of a mutual fund (Fidelity's Magellan Fund) to illustrate the impact that portfolio diversification has on confidence intervals for estimated betas. In addition, we examine a modified estimation approach using excess returns, which are the assets' returns in excess of the risk-free rate.

25-5a Calculating the Beta Coefficient for a Single Stock: Apple

Table 25-1 shows a summary of the data used in this analysis; the full data set is in the file ***Ch25 Tool Kit.xlsx*** and has weekly returns for each week in 2014. Table 25-1 shows the

Skill or Luck?

That's the question *The Wall Street Journal*'s Investment Dartboard Contest sought to answer by comparing the actual investment results of professional analysts against amateurs and dart throwers. Here's how the contest worked. First, *The Wall Street Journal (WSJ)* picked four professional analysts, and each of those pros formed a portfolio by picking four stocks. Second, amateurs could enter the contest by e-mailing their pick of a single stock to the *WSJ,* which then picked four amateurs at random and combined their choices to make a four-stock portfolio. Third, a group of *WSJ* editors formed a portfolio by throwing four darts at the stock tables. At the beginning of each contest, the *WSJ* announced the six resulting portfolios, and at the end of 6 months, the paper announced the results. The top two pros were invited back for the next contest.

In 142 contests, the pros beat the darts 87 times and lost 55 times. The pros also beat the Dow Jones Industrial Average (DJIA) in 54% of the contests. The pros had an average return higher than that of the DJIA, the darts, and the amateurs.

Do these results mean that skill is more important than luck when it comes to investing in stocks? Not necessarily, according to Burton Malkiel, an economics professor at Princeton and the author of the widely read book *A Random Walk Down Wall Street.* Because the dart-selected portfolios consist of randomly chosen stocks, they should have average risk. However, the pros consistently picked high-risk stocks. Because there was a bull market during most of the contests, one would expect high-risk stocks to outperform the average stock. According to Malkiel, the pros' performance could be due as much to a rising market as to superior analytical skills. The *WSJ* discontinued that contest in 2002, so we can't know for sure whether Malkiel was right or wrong.

Until early 2013, the *WSJ* ran a contest pitting six amateurs against six darts. Overall, readers won 19 contests and the darts won 30. The *WSJ* now offers a number of different investment games at **www.marketwatch.com/game**.

market returns (defined as the percentage price change of the S&P 500), the stock returns for Apple, and the returns on the Magellan Fund (which is a well-diversified portfolio). The table also shows the risk-free rate, defined as the yield on a short-term (3-month) U.S. Treasury bill, which we will use later in this analysis.

resource

*See **Ch25 Tool Kit.xlsx** on the textbook's Web site.*

As Table 25-1 shows, Apple had an average annual return of 39.9% during 2014, while the market had an average annual return of 13.2%. As we noted before, it is usually unreasonable to think that the future expected return for a stock will equal its average historical return over a relatively short period, such as 52 weeks. However, we might well expect past volatility to be a reasonable estimate of future volatility, at least during the next year. Observe that the standard deviation for Apple's return during this period was 21.7%, versus 11.2% for the market. Thus, the market's volatility is much less than that of Apple. This is what we would expect, because the market is a well-diversified portfolio and thus much of its risk has been diversified away. The correlation between Apple's stock returns and the market returns is about 0.47, which is a little higher than the correlation for a typical stock.

TABLE 25-1
Summary of Data for Calculating Beta (Weekly Returns during the Year 2014)

	r_M, Market Return (S&P 500 Index)	r_i, Apple Return	r_p, Fidelity Magellan Fund Return	r_{RF}, Risk-Free Rate (Yield on 3-Month T-Bill)
Average return (annualized)	13.2%	39.9%	15.5%	0.034%
Standard deviation (annual)	11.2%	21.7%	12.2%	0.002%
Correlation with market return, ρ		0.47	0.97	0.12

Figure 25-8 shows a plot of Apple's returns against the market's returns. We used the *Excel* Trendline feature to plot the trendline and show the estimated regression equation on the chart. We also used *Excel*'s regression analysis feature (Data, Data Analysis, Regression) to estimate the regression equation. Table 25-2 reports some of these regression results for Apple. Its estimated beta, which is the slope coefficient in the regression, is about 0.90.

As with all regression results, Apple's estimated beta of 0.90 is just an estimate, not necessarily the true value of beta. Table 25-2 also shows the t-statistic and the probability that the true beta is zero. For Apple, this probability is approximately equal to zero. This means that there is virtually a zero chance that the true beta is equal to zero. Because this probability is less than 5%, statisticians would say that the slope coefficient, beta, is "statistically significant." The output of the regression analysis also gives us the 95% confidence interval for the estimate of beta. For Apple, the results tell us that we can be 95% confident that the true beta is between 0.42 and 1.39. This is an extremely wide range, but it is typical for most individual stocks. Therefore, the regression estimate for the beta of any single company is highly uncertain.

Observe also that the points in Figure 25-8 are not clustered very tightly around the regression line. Sometimes Apple does much better than the market; other times, it does much worse. The R^2 value shown in the chart measures the degree of dispersion about the regression line. (Statistically speaking, it measures the proportion of variation that is explained by the regression equation.) An R^2 of 1.0 indicates that all points lie exactly on the line; in this case, all of the variation in the y variable is explained by the x variable. The R^2 for Apple is about 0.22, which is typical of individual stocks. This indicates that about 78% of the variation in Apple's returns is *not* explained by the overall market return.

TABLE 25-2
Regression Results for Calculating Beta

	Regression Coefficient	t-Statistic	Probability of t-Statistic	Lower 95% Confidence Interval	Upper 95% Confidence Interval
Panel A: Apple (Market model)					
Intercept	0.0054	1.43	15.97%	−0.002	0.013
Slope (beta)	0.9024	3.75	0.05%	0.419	1.386
Panel B: Magellan Fund (Market model)					
Intercept	0.0003	0.51	61.55%	−0.001	0.001
Slope (beta)	1.0526	28.57	0.00%	0.979	1.127
Panel C: Apple (CAPM: Excess returns)					
Intercept	0.0054	1.43	15.97%	−0.002	0.013
Slope (beta)	0.9025	3.75	0.05%	0.419	1.386

Source: See the file ***Ch25 Tool Kit.xlsx.***

Note: The market model uses actual historical returns; the CAPM model uses returns in excess of the risk-free rate.

Finally, note that the intercept shown in the regression equation displayed on the chart is about 0.0054. Because the regression equation is based on weekly data, this means that Apple had a 28% annual return that was *not* explained by the CAPM model: $0.0054(52) = 0.28 = 28\%$. However, the regression results in Table 25-2 also show that the probability of the t-statistic is 16% (which is much greater than 5%), meaning that the "true" intercept might be zero even though the estimated intercept was 0.0054. Therefore, most statisticians would say that this intercept is not statistically significant—the returns of Apple are so volatile that we cannot be sure the true intercept is not equal to zero. Translating statistician-speak into plain English, this means that the part of Apple's average weekly return that is *not* explained by the CAPM could, in fact, be zero. Thus, the CAPM might very well explain all of Apple's average weekly returns.

25-5b The Market Model versus the CAPM

When we estimated beta, we used the following regression equation:

$$\bar{r}_{i,t} = a_i + b_i \bar{r}_{M,t} + e_{i,t} \quad (25\text{-}10)$$

where

$\bar{r}_{i,t}$ = Historical (realized) rate of return on Stock i in period t
$\bar{r}_{M,t}$ = Historical (realized) rate of return on the market in period t
a_i = Vertical axis intercept term for Stock i
b_i = Slope, or beta coefficient, for Stock i
$e_{i,t}$ = Random error, reflecting the difference between the actual return on Stock i in a given period and the return as predicted by the regression line

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Equation 25-10 is called the **market model**, because it regresses the stock's return against the market's return. However, the SML of the CAPM for realized returns is a little different from Equation 25-10:

$$\text{SML for realized returns: } \bar{r}_{i,t} = \bar{r}_{RF,t} + b_i(\bar{r}_{M,t} - \bar{r}_{RF,t}) + e_{i,t} \quad \textbf{(25-11)}$$

where $\bar{r}_{RF,t}$ is the historical (realized) risk-free rate in period t.

In order to use the CAPM to estimate beta, we must rewrite Equation 25-11 as a regression equation by adding an intercept, a_i. The result is:

$$(\bar{r}_i - \bar{r}_{RF,t}) = a_i + b_i(\bar{r}_{M,t} - \bar{r}_{RF,t}) + e_{i,t} \quad \textbf{(25-12)}$$

Therefore, to be theoretically correct when estimating beta, we should use the stock's return in excess of the risk-free rate as the y variable and use the market's return in excess of the risk-free rate as the x variable. We did this for Apple using the data in ***Ch25 Tool Kit.xlsx*** (which are summarized in Table 25-1); the results are reported in Panel C of Table 25-2. Note that there are no appreciable differences between the results in Panel A, the market model, and in Panel C, the CAPM model. This typically is the case, so we will use the market model in the rest of the book.

25-5c Calculating the Beta Coefficient for a Portfolio: The Magellan Fund

Let's calculate beta for Fidelity's Magellan Fund, which is a well-diversified portfolio. Figure 25-9 shows the plot of Magellan's weekly returns versus the market's weekly returns. Note the differences between this chart and the one for Apple shown in Figure 25-8. The points for Magellan are tightly clustered around the regression line, indicating that the vast majority of Magellan's variability is explained by the stock market. The R^2 of over 0.94 confirms this visual conclusion. We can also see from Table 25-1 that the Magellan Fund has a standard deviation of 12.2%, which is similar to the 11.2% standard deviation of the market.

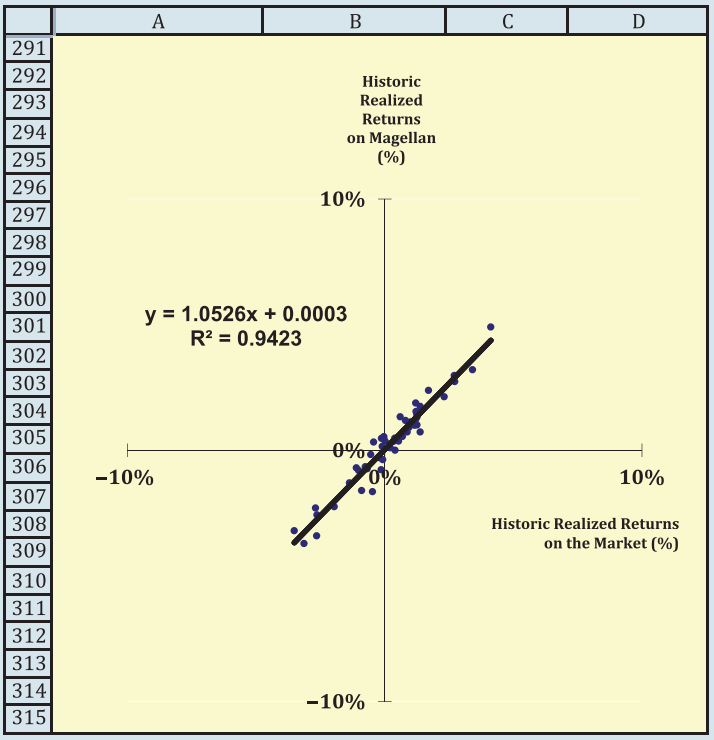
As Table 25-2 shows, Magellan's estimated beta is 1.05 and the 95% confidence interval is from 0.979 to 1.127, which is much tighter than the confidence interval for Apple's estimated beta. Magellan's intercept is virtually zero, and the probability of the intercept's t-statistic is much greater than 5%. Therefore, the intercept is statistically insignificant, indicating that the CAPM explains the average weekly return of the Magellan Fund very well.

resource

*See **Ch25 Tool Kit.xlsx** on the textbook's Web site for all calculations for these performance measures.*

25-5d Performance Measures

Mutual fund managers are often evaluated by their risk-adjusted performance. The three most widely used measures are *Jensen's alpha, Sharpe's reward-to-variability ratio,* and *Treynor's reward-to-volatility ratio*.



JENSEN'S ALPHA

Consider the intercept in the CAPM regression of excess returns, shown in Equation 25-12 and repeated here for convenience:

$$(\bar{r}_i - \bar{r}_{RF,t}) = a_i + b_i(\bar{r}_{M,t} - \bar{r}_{RF,t}) + e_{i,t}$$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

FIGURE 25-9
Calculating a Beta Coefficient for Fidelity's Magellan Fund

Source: See the file ***Ch25 Tool Kit.xlsx.***

For regression equations that have an intercept, the error terms (e_{it}) have an average value of zero Therefore, the estimated intercept, a_i, is the average return that is not explained by the excess market return. In the context of portfolio performance, this intercept is called **Jensen's alpha**.

For the Magellan Fund, the intercept is 1.52% per year (see ***Ch25 Tool Kit.xlsx*** for all calculations). This indicates that the Magellan Fund had slightly better performance than can be explained by the CAPM. However, statistically, this intercept is not significantly different from zero. Its t-statistic is 0.51, which is so low a value that it could happen about 62% of the time by chance even if the intercept were truly zero. When this probability is greater than 5%, as is the case for Magellan, then most statisticians would be reluctant to conclude that Magellan's *estimated* excess return of 1.52% is not *actually* equal to zero.

SHARPE'S REWARD-TO-VARIABILITY RATIO

Sharpe's reward-to-variability ratio is defined as the portfolio's average return (in excess of the risk-free rate) divided by its standard deviation:

$$\text{Sharpe ratio} = \frac{r_{p,Avg} - r_{RF,Avg}}{\sigma \text{ of} (r_{p,Avg} - r_{RF,Avg})} \quad (25\text{-}13)$$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

The Sharpe ratio measures the amount of return per unit risk. For performance evaluation, compare the Sharpe ratio of a portfolio with the Sharpe ratio of a benchmark asset. For example, suppose the S&P 500 is benchmark for the Magellan Fund. Sharpe's ratio for Magellan is 1.26, which is a little greater than the S&P's measure of 0.95. This indicates that the Magellan Fund earned a higher return per unit risk than the S&P 500 earned.

TREYNOR'S REWARD-TO-VOLATILITY RATIO

Treynor's reward-to-volatility ratio is defined as the portfolio's average return (in excess of the risk-free rate) divided by its beta:

$$\text{Treynor ratio} = \frac{r_{p,Avg} - r_{RF,Avg}}{b_p} \quad (25\text{-}14)$$

The Treynor ratio measures the return per unit of risk as measured by beta. For Magellan, the Treynor ratio is 14.6%, which is a little better than the S&P 500's ratio of 13.3%. All in all, the Magellan Fund seems to have slightly overperformed the market, but perhaps not by a statistically significant amount. Although it's not clear whether Magellan "beat the market," it did dramatically reduce the risk faced by investors as compared with the risk inherent in a randomly chosen individual stock.

25-5e Additional Insights into Risk and Return

The CAPM provides some additional insights into the relationship between risk and return.

1. The relationship between a stock's total risk, market risk, and diversifiable risk can be expressed as follows:

$$\text{Total risk} = \text{Variance} = \text{Market risk} + \text{Diversifiable risk}$$
$$\sigma_i^2 = b_i^2\sigma_M^2 + \sigma_{e_i}^2 \quad (25\text{-}15)$$

   Here σ_i^2 is the variance (or total risk) of Stock i, σ_M^2 is the variance of the market, b_i is Stock i's beta coefficient, and $\sigma_{e_i}^2$ is the variance of Stock i's regression error term.
2. If all the points in Figure 25-8 had plotted exactly on the regression line, then the variance of the error term, $\sigma_{e_i}^2$, would have been zero, and all of the stock's total risk would have been market risk. On the other hand, if the points were widely scattered about the regression line, then much of the stock's total risk would be diversifiable. The shares of a large, well-diversified mutual fund will plot very close to the regression line.
3. Beta is a measure of relative market risk, but the *actual* market risk of Stock i is $b_i^2\sigma_M^2$. Market risk can also be expressed in standard deviation form, $b_i\sigma_M$. Therefore, stocks with higher betas have greater market risk. If beta were zero, the stock would have no market risk, whereas if beta were 1.0, then the stock would be exactly as risky as the market—assuming the stock is held in a diversified portfolio—and the stock's market risk would be σ_M.

25-5f Modifying the Historical Beta

Betas are generally estimated from the stock's characteristic line by running a linear regression between past returns on the stock in question and past returns on some

market index. We define betas developed in this manner as **historical betas**. However, in most situations, it is the *future* beta that is needed. This has led to the development of two different types of betas: (1) adjusted betas and (2) fundamental betas.

Adjusted betas grew largely out of the work of Marshall E. Blume, who showed that true betas tend to move toward 1.0 over time.[9] Therefore, we can begin with a firm's pure historical statistical beta, make an adjustment for the expected future movement toward 1.0, and produce an adjusted beta that will, on average, be a better predictor of the future beta than the unadjusted historical beta would be. *Value Line* publishes betas based on approximately this formula:

$$\text{Adjusted beta} = 0.67(\text{Historical beta}) + 0.35(1.0) \quad (25\text{-}16)$$

Consider American Camping Corporation (ACC), a retailer of supplies for outdoor activities. ACC's historical beta is 1.2. Therefore, its adjusted beta is

$$\text{Adjusted beta} = 0.67(1.2) + 0.35(1.0) = 1.15$$

Other researchers have extended the adjustment process to include such fundamental risk variables as financial leverage, sales volatility, and the like. The end product here is a **fundamental beta**, which is constantly adjusted to reflect changes in a firm's operations and capital structure. In contrast, with historical betas (including adjusted ones), such changes might not be reflected until several years after the company's "true" beta had changed.

Adjusted betas obviously are heavily dependent on unadjusted historical betas, and so are fundamental betas as they are actually calculated. Therefore, the plain old historical beta, calculated as the slope of the characteristic line, is important even if one goes on to develop a more exotic version.

25-5g Choice of Estimation Period, Holding Period, and Market Index

When calculating betas from past returns, you must choose the sample estimation period, which is the amount of calendar time over which you gather past returns. You must also choose the holding period over which you measure returns, such as weekly returns. Finally, you must choose an index to represent the market portfolio. Following is a discussion of each choice.

LENGTH OF ESTIMATION PERIOD

Betas can be based on historical periods of different lengths. For example, data for the past 1 year, 3 years, 5 years, or even 10 years may be used. Estimated betas can vary significantly for different choices of estimation periods. For example, the beta estimated from 1 year of data might be very different from the beta estimated from 5 years of data, especially if the company has undergone operating changes or shifts in capital structure during the 5-year period. Because changes in a company's operations or financing can change its beta, most analysts use only 1 to 3 years of past data to estimate beta.

[9]See Marshall E. Blume, "Betas and Their Regression Tendencies," *Journal of Finance*, June 1975, pp. 785–796; and Marshall E. Blume, "On the Assessment of Risk," *Journal of Finance*, March 1971, pp. 1–10.

HOLDING PERIOD FOR MEASURING RETURNS

Returns may be calculated over holding periods of different lengths—a day, a week, a month, a quarter, a year, and so on. For example, if data on NYSE stocks are analyzed over a 2-year period, then we might obtain $52(2) = 104$ weekly returns for a stock and for the market index. Alternatively, we could use monthly returns, which would provide 24 observations in the sample period: $12(2) = 24$. Or we could use daily returns, which would provide about 524 observations in the 2-year period (there are about 252 trading days in a year).

Given the choice of holding period for returns and length of the estimation period, the stock returns would be regressed on the corresponding market returns to obtain the stock's beta. In statistical analysis, it is generally better to have more rather than fewer observations, because using more observations generally leads to greater statistical confidence. This suggests the use of weekly returns and, say, 5 years of data for a sample size of 260, or even daily returns for a still larger sample size. However, the shorter the holding period, the more likely the data are to exhibit random "noise." Also, the greater the number of years of data, the more likely the company's basic risk position has changed. Thus, the choice of both the number of years of data and the length of the holding period for calculating rates of return involves trade-offs between the preference for many observations and a desire to rely on more recent and thus more relevant data.

CHOICE OF MARKET INDEX

The value used to represent "the market" is also an important consideration, because the index that is used can have a significant effect on the calculated beta. Many analysts today use the New York Stock Exchange Composite Index (based on more than 2,000 common stocks, weighted by the value of each company), but others use the S&P 500 Index. In theory, a broader index yields a more theoretically correct estimate of beta. Indeed, the theoretical index should include returns on all stocks, bonds, leases, private businesses, real estate, and even "human capital." As a practical matter, however, we cannot get accurate returns data on most other types of assets, so measurement problems largely restrict us to stock indexes.

OUR RECOMMENDATION

Where does this leave financial managers regarding the proper beta? We recommend estimating your own beta using daily returns for 1 to 2 years. This seems to be the "sweet" spot that provides the tightest confidence intervals for the estimated betas. Shorter estimation periods don't have enough observations, whereas longer estimation periods have problems associated with betas changing during the estimation period. We also recommend adjusting the estimated beta using Equation 25-15.

If you don't estimate your own betas, we recommend *Value Line* because it estimates betas similarly to the way we recommend. Alternatively, you could get betas from several online sources and average them together for a final estimate.

SELF-TEST

*Explain the meaning and significance of a stock's beta coefficient. Illustrate your explanation by drawing, on one graph, the characteristic lines for stocks with low, average, and high risk. (*Hint: *Let your three characteristic lines intersect at $\bar{r}_i = \bar{r}_M = 6\%$, the assumed risk-free rate.)*

What is a typical R^2 for the characteristic line of an individual stock? For a portfolio?

What is the market model? How is it different from the SML for the CAPM?

How are total risk, market risk, and diversifiable risk related?

25-6 Empirical Tests of the CAPM

Does the CAPM's SML produce reasonable estimates for a stock's required return? The literature dealing with empirical tests of the CAPM is quite extensive, so we can give here only a synopsis of some of the key work.

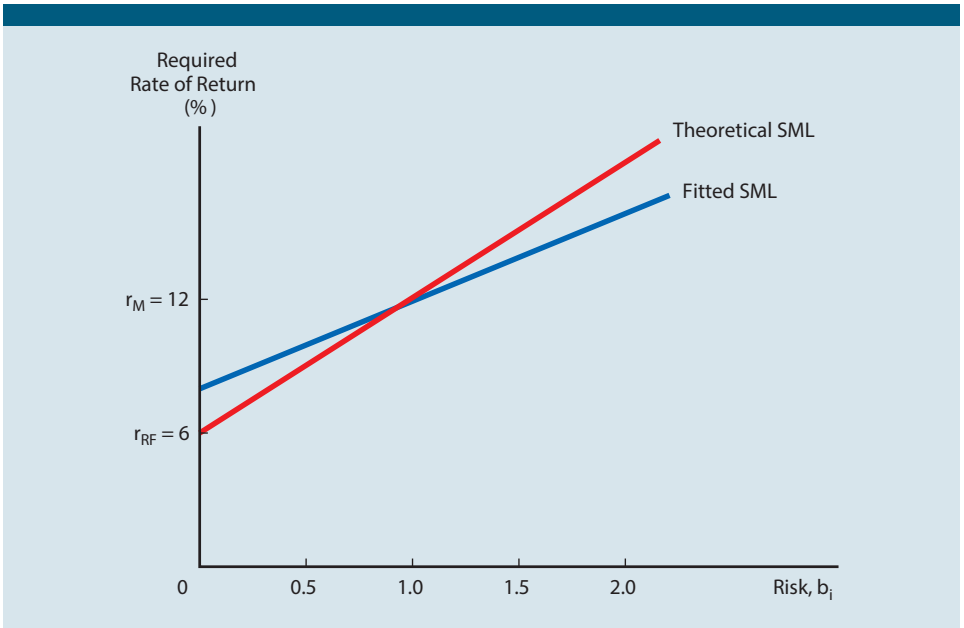
25-6a Tests of the Stability of Beta Coefficients

According to the CAPM, the beta used to estimate a stock's market risk should reflect investors' estimates of the stock's *future* variability in relation to that of the market. Obviously, we do not know now how a stock will be related to the market in the future, nor do we know how the average investor views this expected future relative variability. All we have are data on past variability, which we can use to plot the characteristic line and to calculate *historical betas.* If historical betas have been stable over time, then there would seem to be reason for investors to use past betas as estimators of future variability. For example, if Stock i's beta had been stable in the past, then its historical b_i would probably be a good proxy for its *ex ante,* or expected, beta. By "stable" we mean that if b_i were calculated with data from the period of, say, 2012 to 2016, then this same beta (approximately) should be found from 2017 to 2021.

Robert Levy, Marshall Blume, and others have studied in depth the question of beta stability.[10] Levy calculated betas for individual securities, as well as for portfolios of securities, over a range of time intervals. He reached two conclusions: (1) The betas of individual stocks are unstable and hence past betas for *individual securities* are *not* good estimators of their future risk. (2) Betas of portfolios of ten or more randomly selected stocks are reasonably stable and hence past *portfolio* betas are good estimators of future portfolio volatility. In effect, the errors in individual securities' betas tend to offset one another in a portfolio. The work of Blume and others supports this position.

The conclusion that follows from the beta stability studies is that the CAPM is a better concept for structuring investment portfolios than it is for estimating the required return for individual securities.[11]

25-6b Tests of the CAPM Based on the Slope of the SML



The CAPM states that a linear relationship exists between a security's required rate of return and its beta. Moreover, when the SML is graphed, the vertical axis intercept should be r_{RF}, and the required rate of return for a stock (or portfolio) with $b = 1.0$ should be r_M, the required rate of return on the market. Various researchers have attempted to test the validity of the CAPM by first calculating betas and then plotting subsequent realized rates of return in graphs such as that in Figure 25-10. Second, researchers then determine whether the results conform to three CAPM implications: (1) Is the intercept equal to r_{RF}? (2) Is the plot is linear or curved? (3) Is the slope of the line equal to, $r_M - r_{RF}$? Monthly or daily historical rates of return are generally used for stocks, and both 30-day Treasury bill rates and long-term Treasury bond rates have been used to estimate the value of r_{RF}. Also, most of the studies actually analyzed portfolios rather than individual securities because security betas are so unstable.

[10]See Robert A. Levy, "On the Short-Term Stationarity of Beta Coefficients," *Financial Analysts Journal*, November/December 1971, pp. 55–62; and Marshall E. Blume, "Betas and Their Regression Tendencies," *Journal of Finance*, June 1975, pp. 785–796.

FIGURE 25-10
Tests of the CAPM

Before discussing the results of the tests, it is critical to recognize that although the CAPM is an *ex ante*, or forward-looking, model, the data used to test it are entirely historical. This presents a problem, for there is no reason to believe that *realized* rates of return over past holding periods are necessarily equal to the rates of return to *expect* in the future. Also, historical betas may or may not reflect expected future risk. This lack of *ex ante* data makes it extremely difficult to test the CAPM, but here is a summary of the key results.

1. The evidence generally shows a significant positive relationship between realized returns and beta. However, the intercept usually is a bit higher than predicted by the CAPM and the slope usually is smaller than that predicted by the CAPM.
2. The relationship between risk and return appears to be linear. Empirical studies give no evidence of significant curvature in the risk–return relationship.
3. Tests that attempt to assess the relative importance of market- and company-specific risk do not yield conclusive results. The CAPM implies that company-specific risk should not be relevant, yet both kinds of risk appear to be positively related to security returns; that is, higher returns seem to be required to compensate for diversifiable as well as market risk. However, it may be that the observed relationships reflect statistical problems rather than the true nature of capital markets.
4. Richard Roll has questioned whether it is even conceptually possible to test the CAPM.[12] Roll showed that the linear relationship that prior researchers had observed in graphs like Figure 25-10 resulted from the mathematical properties of the models being tested; therefore, a finding of linearity would prove nothing whatsoever about the CAPM's validity. Roll's work did not disprove the CAPM,

[12]See Richard Roll, "A Critique of the Asset Pricing Theory's Tests," *Journal of Financial Economics*, March 1977, pp. 129–176.

but it did demonstrate the virtual impossibility of proving that investors behave in accordance with its predictions.

5. If the CAPM were completely valid, then it should apply to all financial assets, including bonds. In fact, when bonds are introduced into the analysis, they do *not* plot on the SML. This is worrisome, to say the least.

25-6c Current Status of the CAPM

The CAPM is extremely appealing on an intellectual level: It is logical and rational, and once someone works through and understands the theory, his or her reaction is usually to accept it without question. However, doubts begin to arise when one thinks about the assumptions upon which the model is based, and these doubts are as much reinforced as reduced by the empirical tests. Our own views on the CAPM's current status are as follows.

1. The CAPM framework, with its focus on market as opposed to stand-alone risk, is clearly a useful way to think about the risk of assets. Thus, as a conceptual model, the CAPM is fundamentally important.
2. When applied in practice, the CAPM appears to provide neat, precise answers to important questions about risk and required rates of return. However, the answers are less clear than they seem. The simple truth is that we do not know precisely how to measure any of the inputs required to implement the CAPM. These inputs should all be *ex ante,* yet only *ex post* data are available. Furthermore, historical data on $\bar{r}_M$, r_{RF}, and betas vary greatly depending on the time period studied and the methods used to estimate them. Thus, even though the CAPM appears to be precise, estimates of r_i found through its use are subject to potentially large errors.[13]
3. Because the CAPM is logical in the sense that it represents the way risk-averse people ought to behave, the model is a useful conceptual tool.
4. It is appropriate to think about many financial problems in a CAPM framework. However, it is also important to recognize the limitations of the CAPM when using it in practice.

SELF-TEST

What are the two major types of tests that have been performed to test the validity of the CAPM? **(beta stability; slope of the SML)** *Explain their results.*

Are there any reasons to question the validity of the CAPM? Explain.

25-7 Arbitrage Pricing Theory

The CAPM is a single-factor model. That is, it specifies risk as a function of only one factor, the security's beta coefficient. Perhaps the risk–return relationship is more complex, with a stock's required return a function of more than one factor. For example, what if investors, because personal tax rates on capital gains are lower than those on dividends, value capital gains more highly than dividends? Then, if two stocks had the same market risk, the stock paying the higher dividend would have the higher required rate of return. In that case, required returns would be a function of two factors: market risk and dividend policy.

[13]For an article supporting a positive link between market risk and expected return, see Felicia Marston and Robert S. Harris, "Risk and Return: A Revisit Using Expected Returns," *The Financial Review*, February 1993, pp. 117–137.

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Further, what if many factors are required to specify the equilibrium risk–return relationship rather than just one or two? Stephen Ross has proposed an approach called the **Arbitrage Pricing Theory (APT)**.[14] The APT can include any number of risk factors, so the required return could be a function of two, three, four, or more factors. We should note at the outset that the APT is based on complex mathematical and statistical theory that goes far beyond the scope of this text. Also, although the APT model is widely discussed in academic literature, practical usage to date has been limited. However, such use may increase, so students should at least have an intuitive idea of what the APT is all about.

The SML states that each stock's required return is equal to the risk-free rate plus the product of the market risk premium times the stock's beta coefficient. If stocks are in equilibrium, then the required return will be equal to the expected return:

$$\hat{r}_i = r_i = r_{RF} + (r_M - r_{RF})b_i$$

The historical realized return, $\bar{r}_i$, which will generally be different from the expected return, can be expressed as follows:[15]

$$\bar{r}_i = \hat{r}_i + (\bar{r}_M - \hat{r}_M)b_i + e_i \quad \textbf{(25-17)}$$

Thus, the realized return, $\bar{r}_i$, will be equal to the expected return, $\hat{r}_i$, plus a positive or negative increment, $(\bar{r}_M - \hat{r}_M)b_i$, which depends jointly on the stock's beta and on whether the market did better or worse than was expected, plus a random error term, e_i.

The market's realized return, $\bar{r}_M$, is in turn determined by a number of factors, including domestic economic activity as measured by gross domestic product (GDP), the strength of the world economy, the level of inflation, changes in tax laws, and so forth. Further, different groups of stocks are affected in different ways by these fundamental factors. So, rather than specifying a stock's return as a function of one factor (return on the market), one could specify required and realized returns on individual stocks as a function of various fundamental economic factors. If this were done, we would transform Equation 25-17 into 25-18:

$$\bar{r}_i = \hat{r}_i + (\bar{r}_1 - \hat{F}_1)b_{i1} + \cdots + (\bar{F}_j - \hat{F}_j)b_{ij} + e_i \quad \textbf{(25-18)}$$

Here,

$\bar{r}_i$ = Realized rate of return on Stock i

$\hat{r}_i$ = Expected rate of return on Stock i

$\bar{F}_j$ = Realized value of economic Factor j

$\hat{F}_j$ = Expected value of Factor j

b_{ij} = Sensitivity of Stock i to economic Factor j

e_i = Effect of unique events on the realized return of Stock i

[14]See Stephen A. Ross, "The Arbitrage Theory of Capital Asset Pricing," *Journal of Economic Theory*, December 1976, pp. 341–360.

[15]To avoid cluttering the notation, we have dropped the subscript t to denote a particular time period.

Equation 25-18 shows that the realized return on any stock is the sum of: (1) the stock's expected return; (2) increases or decreases that depend on unexpected changes in fundamental economic factors, multiplied by the sensitivity of the stock to these changes; and (3) a random term that reflects changes unique to the firm.

Certain stocks or groups of stocks are most sensitive to Factor 1, others to Factor 2, and so forth, and every portfolio's returns depend on what happened to the different fundamental factors. Theoretically, one could construct a portfolio with these two properties: (1) The portfolio is riskless. (2) The net investment in it is zero (some stocks would be sold short, with the proceeds from the short sales being used to buy the stocks held long). Such a zero-investment portfolio must have a zero expected return, or else arbitrage operations would occur and cause the prices of the underlying assets to change until the portfolio's expected return became zero. Using this key insight and the hypothesized risk–return relationship for *actual* returns in Equation 25-18, the APT determines the risk–return relationship for *required* returns (i.e., equivalent of the CAPM's Security Market Line):[16]

$$r_i = r_{RF} + (r_1 - r_{RF})b_{i1} + \cdots + (r_j - r_{RF})b_{ij} \quad \textbf{(25-19)}$$

Here, r_j is the required rate of return on a portfolio that is sensitive only to economic Factor j ($b_{pj} = 1.0$) and has zero sensitivity to all other factors. Thus, for example, $(r_2 - r_{RF})$ is the risk premium on a portfolio with $b_{p2} = 1.0$ and all other $b_{pj} = 0.0$. Note that Equation 25-16 is identical in form to the SML, but it permits a stock's required return to be a function of multiple factors.

To illustrate the APT concept, assume that all stocks' returns depend on only three risk factors: inflation, industrial production, and the aggregate degree of risk aversion (the cost of bearing risk, which we assume is reflected in the spread between the yields on Treasury and low-grade bonds). Further, suppose that: (1) The risk-free rate is 8.0%. (2) The required rate of return is 13% on a portfolio with unit sensitivity ($b = 1.0$) to inflation and zero sensitivities ($b = 0.0$) to industrial production and degree of risk aversion. (3) The required return is 10% on a portfolio with unit sensitivity to industrial production and zero sensitivities to inflation and degree of risk aversion. (4) The required return is 6% on a portfolio (the risk-bearing portfolio) with unit sensitivity to the degree of risk aversion and zero sensitivities to inflation and industrial production. Finally, assume that Stock i has factor sensitivities (betas) of 0.9 to the inflation portfolio, 1.2 to the industrial production portfolio, and −0.7 to the risk-bearing portfolio. Stock i's required rate of return, according to the APT, would be 16.3%:

$$\begin{aligned} r_i &= 8\% + (13\% - 8\%)0.9 + (10\% - 8\%)1.2 + (6\% - 8\%)(-0.7) \\ &= 16.3\% \end{aligned}$$

Note that if the required rate of return on the market were 15.0% and if Stock i had a CAPM beta of 1.1, then its required rate of return, according to the SML, would be 15.7%:

$$r_i = 8\% + (15\% - 8\%)1.1 = 15.7\%$$

The primary theoretical advantage of the APT is that it permits several economic factors to influence individual stock returns, whereas the CAPM assumes that the effect of all factors, except those that are unique to the firm, can be captured in a single measure: the variability of the stock with respect to the market portfolio. Also, the APT requires

[16]See Thomas E. Copeland, J. Fred Weston, and Kuldeep Shastri, *Financial Theory and Corporate Policy*, 4th ed. (Reading, MA: Addison-Wesley, 2005).

Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

fewer assumptions than the CAPM and hence is more general. Finally, the APT does not assume that all investors hold the market portfolio, a CAPM requirement that is clearly not met in practice.

However, the APT faces several major hurdles in implementation, the most severe of which is that the theory does not actually identify the relevant factors. The APT does not tell us what factors influence returns, nor does it indicate how many factors should appear in the model. There is some empirical evidence that only three or four factors are relevant—perhaps inflation, industrial production, the spread between low- and high-grade bonds, and the term structure of interest rates—but no one knows for sure.

The APT's proponents argue that it is not necessary to identify the relevant factors. Researchers use a statistical procedure called factor analysis to develop the APT parameters. Basically, they start with hundreds, or even thousands, of stocks and then create several different portfolios, where the returns on each portfolio are not highly correlated with returns on the other portfolios. Thus, each portfolio is apparently more heavily influenced by one of the unknown factors than are the other portfolios. Then, the required rate of return on each portfolio becomes the estimate for that unknown economic factor, shown as r_j in Equation 25-19. The sensitivities of each individual stock's returns to the returns on that portfolio are the factor sensitivities (betas). Unfortunately, the results of factor analysis are not easily interpreted; hence, it does not provide significant insights into the underlying economic determinants of risk.[17]

SELF-TEST

What is the primary difference between the APT and the CAPM?

What are some disadvantages of the APT?

An analyst has modeled the stock of Brown Kitchen Supplies using a two-factor APT model. The risk-free rate is 5%, the required return on the first factor (r_1) is 10%, and the required return on the second factor (r_2) is 15%. If $b_{i1} = 0.5$ and $b_{i2} = 1.3$, what is Brown's required return? **(20.5%)**

SUMMARY

The primary goal of this chapter was to extend your knowledge of risk and return concepts. The key concepts covered are listed here.

- The **feasible set** of portfolios represents all portfolios that can be constructed from a given set of assets.
- An **efficient portfolio** is one that offers the most return for a given amount of risk or the least risk for a given amount of return.
- The **optimal portfolio** for an investor is defined by the investor's highest possible **indifference curve** that is tangent to the **efficient set** of portfolios.
- The **Capital Asset Pricing Model (CAPM)** describes the relationship between market risk and required rates of return.

[17]For additional discussion of the APT, see Edward L. Bubnys, "Simulating and Forecasting Utility Stock Returns: Arbitrage Pricing Theory vs. Capital Asset Pricing Model," *The Financial Review*, February 1990, pp. 1–23; David H. Goldenberg and Ashok J. Robin, "The Arbitrage Pricing Theory and Cost-of-Capital Estimation: The Case of Electric Utilities," *Journal of Financial Research*, Fall 1991, pp. 181–196; and Ashok Robin and Ravi Shukla, "The Magnitude of Pricing Errors in the Arbitrage Pricing Theory," *Journal of Financial Research*, Spring 1991, pp. 65–82.

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

- The **Capital Market Line (CML)** describes the risk–return relationship for efficient portfolios—that is, for portfolios consisting of a mix of the market portfolio and a riskless asset.
- The **Security Market Line (SML)** is an integral part of the CAPM, and it describes the risk–return relationship for individual assets. The required rate of return for any Stock i is equal to the **risk-free rate** plus the **market risk premium** multiplied by the stock's **beta coefficient**: $r_i = r_{RF} + (r_M - r_{RF})b_i$.
- Stock i's **beta coefficient,** b_i, is a measure of the stock's **market risk**. Beta measures the variability of a security's returns relative to the stock market.
- The beta coefficient is measured by the slope of the stock's **characteristic line**, which is found by regressing past stock returns versus past market returns.
- In contrast to the CAPM, the **Arbitrage Pricing Theory (APT)** hypothesizes that expected stock returns are due to more than one factor.

QUESTIONS

(25-1) Define the following terms, using graphs or equations to illustrate your answers wherever feasible:

a. Portfolio; feasible set; efficient portfolio; efficient frontier
b. Indifference curve; optimal portfolio
c. Capital Asset Pricing Model (CAPM); Capital Market Line (CML)
d. Characteristic line; beta coefficient, b
e. Arbitrage Pricing Theory (APT)

(25-2) Security A has an expected rate of return of 6%, a standard deviation of returns of 30%, a correlation coefficient with the market of −0.25, and a beta coefficient of −0.5. Security B has an expected return of 11%, a standard deviation of returns of 10%, a correlation with the market of 0.75, and a beta coefficient of 0.5. Which security is more risky? Why?

SELF-TEST PROBLEM

Solution Shown in Appendix A

(ST-1) **Risk and Return**

You are planning to invest $200,000. Two securities are available, A and B, and you can invest in either of them or in a portfolio with some of each. You estimate that the following probability distributions of returns are applicable for A and B:

Security A	
P_A	r_A
0.1	−10.0%
0.2	5.0
0.4	15.0
0.2	25.0
0.1	40.0
	$\hat{r}_A = ?$
	$\sigma_A = ?$

Security B	
P_B	r_B
0.1	−30.0%
0.2	0.0
0.4	20.0
0.2	40.0
0.1	70.0
	$\hat{r}_B = 20.0\%$
	$\sigma_B = 25.7\%$

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

a. The expected return for Security B is $\hat{r}_B = 20\%$, and $\sigma_B = 25.7\%$. Find $\hat{r}_A$ and σ_A.
b. Use Equation 25-3 to find the value of w_A that produces the minimum risk portfolio. Assume $\rho_{AB} = -0.5$ for parts b and c.
c. Construct a table giving $\hat{r}_p$ and σ_p for portfolios with $w_A = 1.00, 0.75, 0.50, 0.25, 0.0$, and the minimum risk value of w_A. (*Hint:* For $w_A = 0.75$, $\hat{r}_p = 16.25\%$ and $\sigma_p = 8.5\%$; for $w_A = 0.5$, $\hat{r}_p = 17.5\%$ and $\sigma_p = 11.1\%$; for $w_A = 0.25$, $\hat{r}_p = 18.75\%$ and $\sigma_p = 17.9\%$.)
d. Graph the feasible set of portfolios and identify the efficient frontier of the feasible set.
e. Suppose your risk–return trade-off function, or indifference curve, is tangent to the efficient set at the point where $\hat{r}_p = 18\%$. Use this information, together with the graph constructed in part d, to locate (approximately) your optimal portfolio. Draw in a reasonable indifference curve, indicate the percentage of your funds invested in each security, and determine the optimal portfolio's σ_p and $\hat{r}_p$. (*Hint:* Estimate σ_p and $\hat{r}_p$ graphically; then use the equation for $\hat{r}_p$ to determine w_A.)
f. Now suppose a riskless asset with a return $r_{RF} = 10\%$ becomes available. How would this change the investment opportunity set? Explain why the efficient frontier becomes linear.
g. Given the indifference curve in part e, would you change your portfolio? If so, how? (*Hint:* Assume that the indifference curves are parallel.)
h. What are the beta coefficients of Stocks A and B? (*Hint:* Recognize that $r_i = r_{RF} + b_i(r_M - r_{RF})$ and then solve for b_i; assume that your preferences match those of most other investors.)

PROBLEMS

Answers Are in Appendix B

EASY PROBLEMS 1–2

(25-1) Beta

The standard deviation of stock returns for Stock A is 40%. The standard deviation of the market return is 20%. If the correlation between Stock A and the market is 0.70, then what is Stock A's beta?

(25-2) APT

An analyst has modeled the stock of Crisp Trucking using a two-factor APT model. The risk-free rate is 6%, the expected return on the first factor (r_1) is 12%, and the expected return on the second factor (r_2) is 8%. If $b_{i1} = 0.7$ and $b_{i2} = 0.9$, what is Crisp's required return?

INTERMEDIATE PROBLEMS 3–4

(25-3) Two-Asset Portfolio

Stock A has an expected return of 12% and a standard deviation of 40%. Stock B has an expected return of 18% and a standard deviation of 60%. The correlation coefficient between Stocks A and B is 0.2. What are the expected return and standard deviation of a portfolio invested 30% in Stock A and 70% in Stock B?

(25-4) SML and CML Comparison

The beta coefficient of an asset can be expressed as a function of the asset's correlation with the market as follows:

$$b_i = \frac{\rho_{iM}\sigma_i}{\sigma_M}$$

a. Substitute this expression for beta into the Security Market Line (SML), Equation 25-9. This results in an alternative form of the SML.
b. Compare your answer to part a with the Capital Market Line (CML), Equation 25-6. What similarities do you observe? What conclusions can you draw?

CHALLENGING PROBLEMS 5–6

(25-5) Characteristic Line and Security Market Line

You are given the following set of data:

	Historical Rates of Return	
Year	NYSE	Stock X
1	−26.5%	−14.0%
2	37.2	23.0
3	23.8	17.5
4	−7.2	2.0
5	6.6	8.1
6	20.5	19.4
7	30.6	18.2

a. Use a spreadsheet (or a calculator with a linear regression function) to determine Stock X's beta coefficient.
b. Determine the arithmetic average rates of return for Stock X and the NYSE over the period given. Calculate the standard deviations of returns for both Stock X and the NYSE.
c. Assume that the situation during Years 1 to 7 is expected to prevail in the future (i.e., $\hat{r}_X = \bar{r}_{X,\text{Average}}$, $\hat{r}_M = \bar{r}_{M,\text{Average}}$, and both σ_X and b_X in the future will equal their past values). Also assume that Stock X is in equilibrium—that is, it plots on the Security Market Line. What is the risk-free rate?
d. Plot the Security Market Line.
e. Suppose you hold a large, well-diversified portfolio and are considering adding to that portfolio either Stock X or another stock, Stock Y, which has the same beta as Stock X but a higher standard deviation of returns. Stocks X and Y have the same expected returns: $\hat{r}_X = \hat{r}_Y = 10.6\%$. Which stock should you choose?

(25-6) Characteristic Line

You are given the following set of data:

	Historical Rates of Return	
Year	NYSE	Stock Y
1	4.0%	3.0%
2	14.3	18.2
3	19.0	9.1
4	−14.7	−6.0
5	−26.5	−15.3
6	37.2	33.1
7	23.8	6.1
8	−7.2	3.2
9	6.6	14.8
10	20.5	24.1
11	30.6	18.0
	Mean = 9.8%	9.8%
	σ = 19.6%	13.8%

Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

a. Construct a scatter diagram showing the relationship between returns on Stock Y and the market. Use a spreadsheet or a calculator with a linear regression function to estimate beta.
b. Give a verbal interpretation of what the regression line and the beta coefficient show about Stock Y's volatility and relative risk as compared with those of other stocks.
c. Suppose the regression line were exactly as shown by your graph from part b but the scatter plot of points was more spread out. How would this affect: (1) the firm's risk if the stock is held in a one-asset portfolio, and (2) the actual risk premium on the stock if the CAPM holds exactly?
d. Suppose the regression line were downward sloping and the beta coefficient were negative. What would this imply about: (1) Stock Y's relative risk, (2) its correlation with the market, and (3) its probable risk premium?

SPREADSHEET PROBLEM

(25-7) Feasible Portfolios

Start with the partial model in the file ***Ch25 P07 Build a Model.xlsx*** from the textbook's Web site. Following is information for the required returns and standard deviations of returns for A, B, and C:

Stock	r_i	σ_i
A	7.0%	33.11%
B	10.0	53.85
C	20.0	89.44

The correlation coefficients for each pair are shown below in a matrix, with each cell in the matrix giving the correlation between the stock in that row and column. For example, $\rho_{AB} = 0.1571$ is in the row for A and the column for B. Notice that the diagonal values are equal to 1 because a variable is always perfectly correlated with itself.

	A	B	C
A	1.0000	0.1571	0.1891
B	0.1571	1.0000	0.1661
C	0.1891	0.1661	1.0000

a. Suppose a portfolio has 30% invested in A, 50% in B, and 20% in C. What are the expected return and standard deviation of the portfolio?
b. The partial model lists six different combinations of portfolio weights. For each combination of weights, find the required return and standard deviation.
c. The partial model provides a scatter diagram showing the required returns and standard deviations already calculated. This provides a visual indicator of the feasible set. If you seek a return of 10.5%, then what is the smallest standard deviation that you must accept?

MINI CASE

You have been hired at the investment firm of Bowers & Noon. One of its clients doesn't understand the value of diversification or why stocks with the biggest standard deviations don't always have the highest expected returns. Your assignment is to address the client's concerns by showing the client how to answer the following questions.

a. Suppose Asset A has an expected return of 10% and a standard deviation of 20%. Asset B has an expected return of 16% and a standard deviation of 40%. If the correlation between A and B is 0.35, what are the expected return and standard deviation for a portfolio consisting of 30% Asset A and 70% Asset B?
b. Plot the attainable portfolios for a correlation of 0.35. Now plot the attainable portfolios for correlations of +1.0 and −1.0.
c. Suppose a risk-free asset has an expected return of 5%. By definition, its standard deviation is zero, and its correlation with any other asset is also zero. Using only Asset A and the risk-free asset, plot the attainable portfolios.
d. Construct a plausible graph that shows risk (as measured by portfolio standard deviation) on the x-axis and expected rate of return on the y-axis. Now add an illustrative feasible (or attainable) set of portfolios and show what portion of the feasible set is efficient. What makes a particular portfolio efficient? Don't worry about specific values when constructing the graph—merely illustrate how things look with "reasonable" data.
e. Add a set of indifference curves to the graph created for part b. What do these curves represent? What is the optimal portfolio for this investor? Add a second set of indifference curves that leads to the selection of a different optimal portfolio. Why do the two investors choose different portfolios?
f. Now add the risk-free asset. What impact does this have on the efficient frontier?
g. Write out the equation for the Capital Market Line (CML), and draw it on the graph. Interpret the plotted CML. Now add a set of indifference curves and illustrate how an investor's optimal portfolio is some combination of the risky portfolio and the risk-free asset. What is the composition of the risky portfolio?
h. What is the Capital Asset Pricing Model (CAPM)? What are the assumptions that underlie the model? What is the Security Market Line (SML)?
i. What is a characteristic line? How is this line used to estimate a stock's beta coefficient? Write out and explain the formula that relates total risk, market risk, and diversifiable risk.
j. What are two potential tests that can be conducted to verify the CAPM? What are the results of such tests? What is Roll's critique of CAPM tests?
k. Briefly explain the difference between the CAPM and the Arbitrage Pricing Theory (APT).

SELECTED ADDITIONAL CASE

The following case from CengageCompose covers many of the concepts discussed in this chapter and is available at **http://compose.cengage.com.**

CHAPTER 26

Real Options

Honda Motor Company spent $400 million dollars on something it might not need—production flexibility. If demand for its vehicles changed in predictable ways, then Honda would have wasted the $400 million dollars. But as we have seen in the global economic recession, demand for automobiles is highly volatile, with consumer preferences swinging wildly every time oil prices change. To prepare for such volatility, Honda has been building flexibility into its factories and now boasts the most flexibility of any automaker in the United States.

Honda's plant in Liberty, Ohio, can stop Civic production, set up for the CR-V crossover, and start producing CR-Vs in less than 10 minutes, incurring virtually no additional cost in the process. Many of its other plants have similar capabilities. For example, Honda has been able to quickly reduce output of its Ridgeline pickup truck and boost production of more fuel-efficient vehicles. In contrast, Ford will take over a year to convert a factory now producing gas-guzzling sport utility vehicles, with the switchover costing over $75 million. GM has similar problems and will spend $370 million to change models at one of its factories.

Honda's flexibility stems from several factors, beginning with designs for vehicles and production processes that share components and assembly techniques. For example, the assembly process for doors is very similar, no matter what vehicle is being produced. Honda's robots also give it flexibility. For example, the same robots are used to weld different vehicles.

It costs more initially to build in flexibility at a factory, but the payoff can be well worth the cost. As you read this chapter and learn more about options, think about how option pricing techniques can lead to better capital budgeting decisions.

The textbook's Web site contains an Excel *file that will guide you through the chapter's calculations. The file for this chapter is* ***Ch26 Tool Kit.xlsx****, and we encourage you to open the file and follow along as you read the chapter.*

Traditional discounted cash flow (DCF) analysis—in which an asset's cash flows are estimated and then discounted to obtain the asset's NPV—has been the cornerstone for valuing all types of assets since the 1950s. Accordingly, most of our discussion of capital budgeting has focused on DCF valuation techniques. However, in recent years, academics and practitioners have demonstrated that DCF valuation techniques do not always tell the complete story about a project's value and that rote use of DCF can, at times, lead to incorrect capital budgeting decisions.[1]

DCF techniques were originally developed to value securities such as stocks and bonds. Securities are passive investments: Once they have been purchased, most investors have no influence over the cash flows the assets produce. However, real assets are not passive investments, because managerial actions after an investment has been made can influence its results. Furthermore, investing in a new project often brings with it the potential for increasing the firm's future investment opportunities. Such opportunities are, in effect, options—the right (but not the obligation) to take some action in the future. As we demonstrate in the next section, options are valuable, so projects that expand the firm's set of opportunities have positive **option values**. Similarly, any project that reduces the set of future opportunities destroys option value. A project's impact on the firm's opportunities, or its option value, may not be captured by conventional NPV analysis, so this option value should be considered separately, as we do in this chapter.

26-1 Valuing Real Options

Recall from Chapter 11 that **real options** are opportunities for management to change the timing, scale, or other aspects of an investment in response to changes in market conditions. These opportunities are options in the sense that management can, if it is in the company's best interest, undertake some action; management is not *required* to undertake the action. These opportunities are real (as opposed to financial) because they involve decisions regarding real assets—such as plants, equipment, and land—rather than financial assets like stocks or bonds. Four examples of real options are investment timing options, growth options, abandonment options, and flexibility options. This chapter provides an example of how to value an investment timing option and a growth option. ***Web Extension 26A*** on the textbook's Web site shows how to value an **abandonment option**, which allows a company to reduce a project's capacity or drop the project entirely if market conditions deteriorate.

Valuing a real option requires judgment, both to formulate the model and to estimate the inputs. Does this mean the answer won't be useful? Definitely not. For example, the models used by NASA only approximate the centers of gravity for the moon, the Earth, and other heavenly bodies, yet even with these "errors" in their models, NASA has been able to put astronauts on the moon. As one professor said, "All models are wrong, but some are still quite useful." This is especially true for real options. We might not be able to find the exact value of a real option, but the value we find can be helpful in deciding whether or not to accept the project. Equally important, the process of looking for and then valuing real options often identifies critical issues that might otherwise go unnoticed.

[1]For an excellent general discussion of the problems inherent in discounted cash flow valuation techniques as applied to capital budgeting, see Avinash K. Dixit and Robert S. Pindyck, "The Options Approach to Capital Investment," *Harvard Business Review*, May/June 1995, pp. 105–115.

Five possible procedures can be used to deal with real options. Starting with the simplest, they are as follows:

1. Use discounted cash flow (DCF) valuation and ignore any real options by assuming their values are zero.
2. Use DCF valuation and include a qualitative recognition of any real option's value.
3. Use decision-tree analysis.
4. Use a standard model for a financial option.
5. Develop a unique, project-specific model using financial engineering techniques.

The following sections illustrate these procedures.

SELF-TEST

List the five possible procedures for dealing with real options.

26-2 The Investment Timing Option: An Illustration

resource

*All calculations for the analysis of the investment timing option are shown in **Ch26 Tool Kit.xlsx** on the textbook's Web site.*

There is frequently an alternative to investing immediately—the decision to invest or not can be postponed until more information becomes available. By waiting, a better-informed decision can be made, and this **investment timing option** adds value to the project and reduces its risk.

Murphy Systems is considering a project for a new type of handheld device that provides wireless Internet connections. The cost of the project is $50 million, but the future cash flows depend on the demand for wireless Internet connections, which is uncertain. Murphy believes there is a 25% chance that demand for the new device will be high, in which case the project will generate cash flows of $33 million each year for 3 years. There is a 50% chance of average demand, with cash flows of $25 million per year, and a 25% chance that demand will be low and annual cash flows will be only $5 million. A preliminary analysis indicates that the project is somewhat riskier than average, so it has been assigned a cost of capital of 14% versus 12% for an average project at Murphy Systems. Here is a summary of the project's data:

Demand	Probability	Annual Cash Flow
High	0.25	$33 million
Average	0.50	25 million
Low	0.25	5 million
Expected annual cash flow		$22 million
Project's cost of capital	14%	
Life of project	3 years	
Required investment, or cost of project	$50 million	

Murphy could accept the project and implement it immediately; however, because the company has a patent on the device's core modules, it could also choose to delay the decision until next year, when more information about demand will be available. The cost will still be $50 million if Murphy waits, and the project will still be expected to generate the indicated cash flows, but each flow will be pushed back 1 year. However, if Murphy waits, then it will know which of the demand conditions—and hence which set of cash flows—will occur. If Murphy waits, then it will, of course, make the investment only if demand is sufficient to yield a positive NPV.

Observe that this real timing option resembles a call option on a stock. A call gives its owner the right to purchase a stock at a fixed strike price, but only if the stock's price is higher than the strike price will the owner exercise the option and buy the stock. Similarly, if Murphy defers implementation, then it will have the right to "purchase" the project by making the $50 million investment if the NPV as calculated next year, when new information is available, is positive.

26-2a Approach 1: DCF Analysis Ignoring the Timing Option

Based on probabilities for the different levels of demand, the expected annual cash flows are $22 million per year:

$$\begin{aligned}\text{Expected cash flow per year} &= 0.25(\$33) + 0.50(\$25) + 0.25(\$5)\\ &= \$22 \text{ million}\end{aligned}$$

Ignoring the investment timing option, the traditional NPV is $1.08 million, found as follows:

$$\text{NPV} = -\$50 + \frac{\$22}{(1+0.14)^1} + \frac{\$22}{(1+0.14)^2} + \frac{\$22}{(1+0.14)^3} = \$1.08$$

The present value of the cash inflows is $51.08 million while the cost is $50 million, leaving an NPV of $1.08 million.

Based just on this DCF analysis, Murphy should accept the project. Note, however, that if the expected cash flows had been slightly lower—say, $21.5 million per year—then the NPV would have been negative and the project would have been rejected. Also, note that the project is risky: There is a 25% probability that demand will be weak, in which case the NPV will turn out to be a negative $38.4 million.

26-2b Approach 2: DCF Analysis with a Qualitative Consideration of the Timing Option

The discounted cash flow analysis suggests that the project should be accepted, but just barely, and it ignores the existence of a possibly valuable real option. If Murphy implements the project now, it gains an expected (but risky) NPV of $1.08 million. However, accepting now means that it is also giving up the option to wait and learn more about market demand before making the commitment. Thus, the decision is this: Is the option Murphy would be giving up worth more or less than $1.08 million? If the option is worth more than $1.08 million, then Murphy should not give up the option, which means deferring the decision—and vice versa if the option is worth less than $1.08 million.

Based on the discussion of financial options in Chapter 8, what qualitative assessment can we make regarding the option's value? Put another way: Without doing any additional calculations, does it appear that Murphy should go forward now or wait? In thinking about this decision, first note that the value of an option is higher if the current value of the underlying asset is high relative to its strike price, other things held constant. For example, a call option with a strike price of $50 on a stock with a current price of $50 (an at-the-money call) is worth more than if the current price were $20 (an out-of-the-money call). The strike price of the project is $50 million, and our first guess at the value of its cash flows is $51.08 million. We will calculate the exact value of Murphy's underlying asset later, but the DCF analysis does suggest that the underlying asset's value will be close to the strike price, so the option should be valuable. We also know that an option's value

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

is higher the longer its time to expiration. Here the option has a 1-year life, which is fairly long for an option, and this also suggests that the option is probably valuable. Finally, we know that the value of an option increases with the risk of the underlying asset. The data used in the DCF analysis indicate that the project is quite risky, which again suggests that the option is valuable.

Thus, our qualitative assessment indicates that the option to delay might well be more valuable than the expected NPV of $1.08 if we undertake the project immediately. This conclusion is subjective, but the qualitative assessment suggests that Murphy's management should go on to make a quantitative assessment of the situation.

26-2c Approach 3: Scenario Analysis and Decision Trees

Part 1 of Figure 26-1 presents a scenario analysis and decision tree similar to the examples in Chapter 11. Each possible outcome is shown as a "branch" on the tree. Each branch shows the cash flows and probability of a scenario laid out as a time line. Thus, the top line, which gives the payoffs of the high-demand scenario, has positive cash flows of $33 million for the next 3 years, and its NPV is $26.61 million. The average-demand branch in the middle has an NPV of $8.04 million, while the NPV of the low-demand branch is a negative $38.39 million. Because Murphy will suffer a $38.39 million loss if demand is weak, and there is a 25% probability of weak demand, the project is clearly risky.

The expected NPV is the weighted average of the three possible outcomes, where the weight for each outcome is its probability. The weighted sum in the last column in Part 1 shows that the expected NPV is $1.08 million, the same as in the original DCF analysis. Part 1 also shows a standard deviation of $24.02 million for the NPV and a coefficient of variation (defined as the ratio of standard deviation to the expected NPV) of 22.32, which is extremely large. Clearly, the project is quite risky under the analysis thus far.

Part 2 is set up similarly to Part 1 except that it shows what happens if Murphy delays the decision and then implements the project only if demand turns out to be high or average. No cost is incurred now at Year 0—here, the only action is to wait. Then, if demand is average or high, Murphy will spend $50 million at Year 1 and receive either $33 million or $25 million per year for the following 3 years. If demand is low, as shown on the bottom branch, Murphy will spend nothing at Year 1 and will receive no cash flows in subsequent years. The NPV of the high-demand branch is $23.35 million and that of the average-demand branch is $7.05 million. Because all cash flows under the low-demand scenario are zero, the NPV in this case will also be zero. The expected NPV if Murphy delays the decision is $9.36 million.

This analysis shows that the project's expected NPV will be much higher if Murphy delays than if it invests immediately. Also, because there is no possibility of losing money under the delay option, this decision also lowers the project's risk. This plainly indicates that the option to wait is valuable; hence, Murphy should wait until Year 1 before deciding whether to proceed with the investment.

Before we conclude the discussion of decision trees, note that we used the same cost of capital, 14%, to discount cash flows in the "proceed immediately" scenario analysis in Part 1 and under the "delay 1 year" scenario in Part 2. However, this is not appropriate for three reasons. First, because there is no possibility of losing money if Murphy delays, the investment under that plan is clearly less risky than if Murphy charges ahead today. Second, the 14% cost of capital might be appropriate for risky cash flows, yet the investment in the project at Year 1 in Part 2 is known with certainty. Perhaps, then, we should discount it at

69							Coefficient of variation[c] =	0.92

Source: See the file ***Ch26 Tool Kit.xlsx***. Numbers are reported as rounded values for clarity, but are calculated using *Excel*'s full precision. Thus, intermediate calculations using the figure's rounded values will be inexact.

Notes:

[a]The WACC is 14%.

[b]The expected value and standard deviation are calculated as explained in Chapter 6.

[c]The coefficient of variation is the standard deviation divided by the expected value.

[d]The NPV in Part 2 is as of Year 0. Therefore, each of the project cash flows is discounted back 1 more year than in Part 1.

the risk-free rate.[2] Third, the project's cash inflows (excluding the initial investment) are different in Part 2 than in Part 1 because the low-demand cash flows are eliminated. This suggests that if 14% is the appropriate cost of capital in the "proceed immediately" case, then some lower rate would be appropriate in the "delay decision" case.

[2]For a more detailed explanation of the rationale behind using the risk-free rate to discount the project cost, see Timothy A. Luehrman, "Investment Opportunities as Real Options: Getting Started on the Numbers," *Harvard Business Review*, July/August 1998, pp. 51–67. This paper also provides a discussion of real option valuation. Professor Luehrman also wrote a follow-up paper that provides an excellent discussion of the ways real options affect strategy: "Strategy as a Portfolio of Real Options," *Harvard Business Review*, September/October 1998, pp. 89–99.

In Figure 26-2, Part 1, we repeat the "delay decision" analysis but with one exception. We continue to discount the operating cash flows in Year 2 through Year 4 at the 14% WACC, but now we discount the project's cost at Year 1 using the risk-free rate of 6%. This increases the PV of the cost, which lowers the NPV from $9.36 million to $6.88 million. Yet we really don't know the precise WACC for this project—the 14% we used might be too high or too low for the operating cash flows in Year 2 through Year 4.[3] Therefore, in Part 2

Notes:

[a]The operating cash flows in Year 2 through Year 4 are discounted at the WACC of 14%. The cost in Year 1 is discounted at the risk-free rate of 6%.

[b]The expected value and standard deviation are calculated as explained in Chapter 6.

[c]The coefficient of variation is the standard deviation divided by the expected value.

[3]Murphy might gain information by waiting, which could reduce risk, but if a delay would enable others to enter and perhaps preempt the market, this could increase risk. In our example, we assumed that Murphy has a patent on critical components of the device, precluding the entrance of a competitor that could preempt its position in the market.

of Figure 26-2 we show a sensitivity analysis of the NPV in which the discount rates used for both the operating cash flows and for the project's cost vary. This sensitivity analysis shows that, under all reasonable WACCs, the NPV of delaying is greater than $1.08 million. This confirms that the option to wait is more valuable than the $1.08 million NPV resulting from immediate implementation. Therefore, Murphy should wait rather than implement the project immediately.

26-2d Approach 4: Valuing the Timing Option with the Black-Scholes Option Pricing Model

The decision-tree approach, coupled with a sensitivity analysis, may provide enough information for a good decision. However, it is often useful to obtain additional insights into the real option's value, which means using the fourth procedure, an option pricing model. To do this, the analyst must find a standard financial option that resembles the project's real option.[4] As noted earlier, Murphy's option to delay the project is similar to a call option on a stock. Hence, the Black-Scholes option pricing model can be used. This model requires five inputs: (1) the risk-free rate, (2) the time until the option expires, (3) the strike price, (4) the current price of the stock, and (5) the variance of the stock's rate of return. Therefore, we need to estimate values for those five inputs.

First, if we assume that the rate on a 52-week Treasury security is 6%, then this rate can be used as the risk-free rate. Second, Murphy must decide within a year whether or not to implement the project, so there is 1 year until the option expires. Third, it will cost $50 million to implement the project, so $50 million can be used for the strike price. Fourth, we need a proxy for the value of the underlying asset, which in Black-Scholes is the current price of the stock. Note that a stock's current price is the present value of its expected future cash flows. For Murphy's real option, the underlying asset is the project itself, and its current "price" is the present value of its expected future cash flows. Therefore, as a proxy for the stock price we can use the present value of the project's future cash flows. And fifth, the variance of the project's return can be used to represent the variance of the stock's return in the Black-Scholes model.

Figure 26-3 shows how to estimate the present value of the project's cash inflows. We need to find the current value of the underlying asset—that is, the project. For a stock, the current price is the present value of all expected future cash flows, including those that are expected even if we do not exercise the call option. Note also that the strike price for a call option has no effect on the stock's current price.[5] For our real option, the underlying asset is the delayed project, and its current "price" is the present value of all its future expected cash flows. Just as the price of a stock includes all of its future cash flows, so should the present value of the project include all of its possible future cash flows. Moreover, because the price of a stock is not affected by the strike price of a call option, we ignore the project's "strike price," which is its implementation cost, when we find its present value. Figure 26-3 shows the expected cash flows if the project is delayed. The PV of these cash flows as of now (Year 0) is $44.80 million, and this is the input we should use for the current price in the Black-Scholes model.

The last required input is the variance of the project's return. Three different approaches could be used to estimate this input. First, we could use judgment—an educated guess. Here, we would begin by recalling that a company is a portfolio of projects (or assets), with each project having its own risk. Because returns on the company's stock reflect the diversification

[4]In theory, financial option pricing models apply only to assets that are continuously traded in a market. Even though real options usually don't meet this criterion, financial option models often provide a reasonably accurate approximation of the real option's value.

[5]The company itself is not involved with traded stock options. However, if the option were a warrant issued by the company, then the strike price would affect the company's cash flows and hence its stock price.

149							Expected value of PV[b] =	$44.80
150							Standard deviation[b] =	$21.07
151							Coefficient of variation[c] =	0.47

Source: See the file ***Ch26 Tool Kit.xlsx***. Numbers are reported as rounded values for clarity, but are calculated using *Excel*'s full precision. Thus, intermediate calculations using the figure's rounded values will be inexact.

Notes:

[a]Here we find the PV, not the NPV, because the project's cost is ignored. The WACC is 14%. All cash flows in this scenario are discounted back to Year 0.

[b]The expected value and standard deviation are calculated as explained in Chapter 6.

[c]The coefficient of variation is the standard deviation divided by the expected value.

gained by combining many projects, we might expect the variance of the stock's returns to be lower than the variance of one of its average projects. The variance of an average company's stock return is about 0.12, so we might expect the variance for a typical project to be somewhat higher, say, 0.15 to 0.25. Companies in the Internet infrastructure industry are riskier than average, so we might subjectively estimate the variance of Murphy's project to be in the range of 0.18 to 0.30.

The second approach, called the *direct* method, is to estimate the rate of return for each possible outcome and then calculate the variance of those returns. First, Part 1 in Figure 26-4 shows the PV for each possible outcome as of Year 1, the time when the option expires. Here, we simply find the present value of all future operating cash flows discounted back to Year 1, using the WACC of 14%. The Year-1 present value is $76.61 million for high demand, $58.04 million for average demand, and $11.61 million for low demand. Then, in Part 2, we show the percentage return from the current time until the option expires for each scenario, based on the $44.80 million starting "price" of the project at Year 0 as calculated in Figure 26-3. If demand is high, we will obtain a return of 71.0%: $(\$76.61 - \$44.80)/\$44.80 = 0.710 = 71.0\%$. Similar calculations show returns of 29.5% for average demand and −74.1% for low demand. The expected percentage return is 14%, the standard deviation is 53.6%, and the variance is 0.287.[6]

The third approach for estimating the variance of the annual rate of return is also based on the scenario data, but the data are used in a different manner. First, we know

[6]Two points should be made about the percentage return. First, for use in the Black-Scholes model, we need a percentage return calculated as shown, not an IRR return. The IRR is not used in the option pricing approach. Second, the expected return comes to 14%, the same as the WACC. This is because the Year-0 price and the Year-1 PVs were all calculated using the 14% WACC and because we measured return over only 1 year. If we measure the compound return over more than 1 year, then the average return generally will not equal 14%.

that demand is not really limited to three scenarios, which means the direct approach in Figure 26-4 isn't necessarily reliable. We could overcome this problem by estimating thousands of scenarios, but that would require a lot of effort. Fortunately, there is a simple shortcut we can use. From Part 1 of Figure 26-4, we have estimates of the expected value of the project and its standard deviation at the time the option expires. Using this information (and a lot of complicated mathematics), we can estimate the variance of the project's annual rate of return, σ^2, with this formula:[7]

$$\sigma^2 = \frac{\ln(CV^2 + 1)}{t} \quad \textbf{(26-1)}$$

Here CV is the coefficient of variation of the underlying asset's price at the time the option expires, and t is the time until the option expires. Although the three outcomes in the scenarios represent a small sample of the many possible outcomes, we can still use the scenario data to estimate the variance that the project's rate of return would have if there were an infinite number of possible outcomes. For Murphy's project, this indirect method produces the following estimate of the variance of the project's return:

$$\sigma^2 = \frac{\ln(0.47^2 + 1)}{1} = 0.20 \quad \textbf{(26-1a)}$$

Which of the three approaches is best? Obviously, they all involve judgment, so an analyst might want to consider all three. In our example, all three methods produce similar estimates, but for illustrative purposes we will simply use 0.20 as our initial estimate for the variance of the project's rate of return.

In Part 1 of Figure 26-5, we calculate the value of the option to defer investment in the project based on the Black-Scholes model, and the result is $7.04 million. Because this is significantly higher than the $1.08 million NPV under immediate implementation and because the option would be forfeited if Murphy goes ahead right now, we conclude as before that the company should defer the final decision until more information is available.

Many inputs were based on subjective estimates, so it is important to determine how sensitive the final outcome is to key inputs. Therefore, in Part 2 of Figure 26-5 we show the sensitivity of the option's value to different estimates of the variance. It is reassuring to see that, for all reasonable estimates of variance, the option to delay remains more valuable than immediate implementation.

26-2e Approach 5: Financial Engineering

Sometimes an analyst might not be satisfied with the results of a decision-tree analysis and cannot find a standard financial option that corresponds to the real option. In such a situation the only alternative is to develop a unique model for the specific real option being analyzed, a process called **financial engineering**. When financial engineering is applied on

[7]For a more detailed discussion of the relationship between the variance of a stock's price and the variance of its return, see David C. Shimko, *Finance in Continuous Time* (Miami, FL: Kolb Publishing, 1992).

Notes:

[a]The current value of the project is taken from Figure 26-3.

[b]The variance of the project's rate of return is taken from Part 2 of Figure 26-4.

Wall Street, where it was developed, the result is a newly designed financial product.[8] When it is applied to real options, the result is the value of a project that contains embedded options.

Although financial engineering was originally developed on Wall Street, many financial engineering techniques have been applied to real options during the last 20 years. We expect this trend to continue, especially in light of the rapid improvements in computer processing speed and spreadsheet software capabilities. One financial engineering technique is called **risk-neutral valuation**. This technique uses simulation, and we discuss it in ***Web Extension 26B.*** Most other financial engineering techniques are too complicated for a course in financial management, so we leave a detailed discussion of them to a specialized course.

[8]Financial engineering techniques are widely used for the creation and valuation of derivative securities.

SELF-TEST

What is a decision tree?

In a qualitative analysis, what factors affect the value of a real option?

26-3 The Growth Option: An Illustration

As we saw with the investment timing option, there is frequently an alternative to merely accepting or rejecting a static project. Many investment opportunities, if successful, lead to other investment opportunities. The production capacity of a successful product line can later be expanded to satisfy increased demand, or distribution can be extended to new geographic markets. A company with a successful name brand can capitalize on its success by adding complementary or new products under the same brand. These opportunities are **growth options**, which add value to a project and explain, for example, why companies are flocking to make inroads into the very difficult business environment in China.

Kidco Corporation designs and manufactures products aimed at the preteen market. Most of its products have a very short life, given the rapidly changing tastes of preteens. Kidco is now considering a project that will cost $30 million. Management believes there is a 25% chance that the project will "take off" and generate operating cash flows of $34 million in each of the next 2 years, after which preteen tastes will change and the project will be terminated. There is a 50% chance of average demand, in which case cash flows will be $20 million annually for 2 years. Finally, there is a 25% chance that preteens won't like the product at all, and it will generate cash flows of only $2 million per year. The estimated cost of capital for the project is 14%.

Based on its experience with other projects, Kidco believes it will be able to launch a second-generation product if demand for the original product is average or above. This second-generation product will cost the same as the first-generation product, $30 million, and the cost will be incurred at Year 2. However, given the success of the first-generation product, Kidco believes that the second-generation product would be just as successful as the first-generation product.

This growth option resembles a call option on a stock, because it gives Kidco the opportunity to "purchase" a successful follow-on project at a fixed cost if the value of the project is greater than the cost. Otherwise, Kidco will let the option expire by not implementing the second-generation product.

The following sections apply the first four valuation approaches: (1) DCF, (2) DCF and qualitative assessment, (3) decision-tree analysis, and (4) analysis with a standard financial option.

26-3a Approach 1: DCF Analysis Ignoring the Growth Option

Based on probabilities for the different levels of demand, the expected annual operating cash flows for the project are $19 million per year:

$$0.25(\$34) + 0.50(\$20) + 0.25(\$2) = \$19.00$$

Ignoring the growth option, the traditional NPV is $1.29 million:

$$\text{NPV} = -\$30 + \frac{\$19}{(1+0.14)^1} + \frac{\$19}{(1+0.14)^2} = \$1.29$$

Based on this DCF analysis, Kidco should accept the project.

26-3b Approach 2: DCF Analysis with a Qualitative Consideration of the Growth Option

Although the DCF analysis indicates that the project should be accepted, it ignores a potentially valuable real option. The option's time to maturity and the volatility of the underlying project provide qualitative insights into the option's value. Kidco's growth option has 2 years until maturity, which is a relatively long time, and the cash flows of the project are volatile. Taken together, this qualitative assessment indicates that the growth option should be quite valuable.

26-3c Approach 3: Decision-Tree Analysis of the Growth Option

Part 1 of Figure 26-6 shows a scenario analysis for Kidco's project. The top line, which describes the payoffs for the high-demand scenario, has operating cash flows of $34 million for the next 2 years. The NPV of this branch is $25.99 million. The NPV of the average-demand branch in the middle is $2.93 million, and it is −$26.71 million for the low-demand scenario. The sum in the last column of Part 1 shows the expected NPV of $1.29 million. The coefficient of variation is 14.54, indicating that the project is very risky.

Part 2 of Figure 26-6 shows a decision-tree analysis in which Kidco undertakes the second-generation product only if demand is average or high. In these scenarios, shown on the top two branches of the decision tree, Kidco will incur a cost of $30 million at Year 2 and receive operating cash flows of either $34 million or $20 million for the next 2 years, depending on the level of demand. If the demand is low, shown on the bottom branch, Kidco has no cost at Year 2 and receives no additional cash flows in subsequent years. All operating cash flows (which do not include the cost of implementing the second-generation project at Year 2) are discounted at the WACC of 14%. Because the $30 million implementation cost is known, it is discounted at the risk-free rate of 6%. As shown in Part 2 of Figure 26-6, the expected NPV is $4.70 million, indicating that the growth option is quite valuable.

The option itself alters the risk of the project, which means that 14% is probably not the appropriate cost of capital. Figure 26-7 presents the results of a sensitivity analysis in which the cost of capital for the operating cash flows varies from 8% to 18%. The sensitivity analysis also allows the rate used to discount the implementation cost at Year 2 to vary from 3% to 9%. The resulting NPV is positive for all reasonable combinations of discount rates.

26-3d Approach 4: Valuing the Growth Option with the Black-Scholes Option Pricing Model

The fourth approach is to use a standard model for a corresponding financial option. As we noted earlier, Kidco's growth option is similar to a call option on a stock, so we will use the Black-Scholes model to find the value of the growth option. The time until the growth option expires is 2 years. The rate on a 2-year Treasury security is 6%, and this provides a good estimate of the risk-free rate. Implementing the project will cost $30 million, which is the strike price.

The input for stock price in the Black-Scholes model is the current value of the underlying asset. For the growth option, the underlying asset is the second-generation project, and its current value is the present value of its cash flows. The calculations in Figure 26-8 show that this value is $24.07 million. Because the strike price of $30 million is greater than the current "price" of $24.07 million, the growth option is currently out-of-the-money.

Notes:

[a]The operating cash flows are discounted by the WACC of 14%.

[b]The expected value, standard deviation, and variance are calculated as in Chapter 6.

[c]The coefficient of variation is the standard deviation divided by the expected value.

[d]The total cash flows at Year 2 are equal to the operating cash flows for the first-generation product minus the $30 million cost to implement the second-generation product, if the firm chooses to do so. For example, the Year-2 cash flow in the high-demand scenario is $34 − $30 = $4 million. Based on Part 1, it makes economic sense to implement the second-generation product only if demand is high or average.

[e]The operating cash flows in Year 1 through Year 2, which do not include the $30 million cost of implementing the second-generation project at Year 2 for the high-demand and average-demand scenarios, are discounted at the WACC of 14%. The $30 million implementation cost at Year 2 for the high-demand and average-demand scenarios is discounted at the risk-free rate of 6%.

Figure 26-9 shows the estimates for the variance of the project's rate of return using the two methods described earlier in the chapter for the analysis of the investment timing option. The direct method, shown in Part 2 of the figure, produces an estimate of 0.179

for the variance of return. The indirect method, in Part 2, estimates the variance as 0.153. Both estimates are somewhat higher than the 0.12 variance of a typical company's stock return, which is consistent with the idea that a project's variance is higher than a stock's because of diversification effects. Thus, an estimated variance of 0.15 to 0.20 seems reasonable. We use an initial estimate of 0.153 in our initial application of the Black-Scholes model, shown in Part 1 of Figure 26-10.

Using the Black-Scholes model for a call option, Figure 26-10 shows a $4.34 million value for the growth option. The total NPV is the sum of the first-generation project's NPV and the value of the growth option: Total NPV = $1.29 + $4.34 = $5.63 million, which is much higher than the NPV of the first-generation project alone. As this analysis

shows, the growth option adds considerable value to the original project. In addition, the sensitivity analysis in Part 2 of Figure 26-10 indicates that the growth option's value is large for all reasonable values of variance. Kidco should therefore accept the project.

For an illustrative valuation of an abandonment option, see ***Web Extension 26A.***

SELF-TEST

Explain how growth options are like call options.

26-4 Concluding Thoughts on Real Options

We don't deny that real options can be complicated. Keep in mind, however, that 60 years ago very few companies used NPV because it seemed too complicated. Now NPV is a basic tool used by virtually all companies and taught in all business schools. A similar but more rapid pattern of adoption is occurring with real options. Twenty years ago very few companies used real options, but a survey of CFOs reported that more than 26% of companies now use real option techniques when evaluating projects.[9] Just as with NPV, it's only a matter of time before virtually all companies use real option techniques.

We have provided you with some basic tools for evaluating real options, starting with the ability to identify real options and make qualitative assessments regarding a real option's value. Decision trees are another important tool, because they facilitate an explicit identification of the embedded options, which is critical in the decision-making process. However, keep in mind that the decision tree should not use the original project's cost of capital. Although finance theory has not yet provided a way to estimate the appropriate cost of capital for a decision tree, sensitivity analysis can identify the effect that different costs of capital have on the project's value.

Many real options can be analyzed using a standard model for an existing financial option, such as the Black-Scholes model for calls and puts. There are also other financial models for a variety of options. These include the option to exchange one asset for another, the option to purchase the minimum or the maximum of two or more assets, the option on an average of several assets, and even an option on an option.[10] In fact, there are entire textbooks that describe even more options.[11] Given the large number of standard models for existing financial options, it is often possible to find a financial option that resembles the real option being analyzed.

Sometimes there are some real options that don't resemble any financial options. But the good news is that many of these options can be valued using techniques from financial engineering. This is frequently the case if there is a traded financial asset that matches the risk of the real option. For example, many oil companies use oil futures contracts to price the real options that are embedded in various exploration and leasing strategies. With the explosion in the markets for derivatives, there are now financial contracts that span an

incredible variety of risks. This means that an ever-increasing number of real options can be valued using these financial instruments. Most financial engineering techniques are beyond the scope of this book, but ***Web Extension 26B*** on the textbook's Web site describes one particularly useful financial engineering technique called risk-neutral valuation.[12]

SELF-TEST

How widely used is real option analysis?

What techniques can be used to analyze real options?

SUMMARY

In this chapter we discussed some topics that go beyond the simple capital budgeting framework, including the following:

- Investing in a new project often brings with it a potential increase in the firm's future opportunities. Opportunities are, in effect, options—the right but not the obligation to take some future action.
- A project may have an **option value** that is not accounted for in a conventional NPV analysis. Any project that expands the firm's set of opportunities has positive option value.
- **Real options** are opportunities for management to respond to changes in market conditions and involve "real" rather than "financial" assets.
- There are five possible procedures for valuing real options: (1) DCF analysis only, and ignore the real option; (2) DCF analysis and a qualitative assessment of the real option's value; (3) decision-tree analysis; (4) analysis with a standard model for an existing financial option; and (5) financial engineering techniques.
- Many **investment timing options** and **growth options** can be valued using the Black-Scholes call option pricing model.
- See ***Web Extension 26A*** on the textbook's Web site for an illustration of valuing the **abandonment option**.
- See ***Web Extension 26B*** on the textbook's Web site for a discussion of **risk-neutral valuation**.

QUESTIONS

(26-1) Define each of the following terms:

a. Real option; managerial option; strategic option; embedded option
b. Investment timing option; growth option; abandonment option; flexibility option
c. Decision tree

(26-2) What factors should a company consider when it decides whether to invest in a project today or to wait until more information becomes available?

(26-3) In general, do timing options make it more or less likely that a project will be accepted today?

(26-4) If a company has an option to abandon a project, would this tend to make the company more or less likely to accept the project today?

SELF-TEST PROBLEM

Solution Shown in Appendix A

(ST-1)
Real Options

Katie Watkins, an entrepreneur, believes that consolidation is the key to profit in the fragmented recreational equine industry. In particular, she is considering starting a business that will develop and sell franchises to other owner-operators, who will then board and train hunter-jumper horses. The initial cost to develop and implement the franchise concept is $8 million. She estimates a 25% probability of high demand for the concept, in which case she will receive cash flows of $13 million at the end of each year for the next 2 years. She estimates a 50% probability of medium demand, with annual cash flows of $7 million for 2 years, and a 25% probability of low demand, with annual cash flows of $1 million for 2 years. She estimates the appropriate cost of capital is 15%. The risk-free rate is 6%.

a. Find the NPV of each scenario, and then find the expected NPV.
b. Now assume that the expertise gained by taking on the project will lead to an opportunity at the end of Year 2 to undertake a similar venture that will have the same cost as the original project. The new project's cash flows would follow whichever branch resulted for the original project. In other words, there would be an $8 million cost at the end of Year 2 and then cash flows of $13 million, $7 million, or $1 million for Years 3 and 4. Use decision-tree analysis to estimate the combined value of the original project and the additional project (but implement the additional project only if it is optimal to do so). Assume that the $8 million cost at Year 2 is known with certainty and should be discounted at the risk-free rate of 6%. (*Hint:* Do one decision tree that discounts the operating cash flows at the 15% cost of capital and another decision tree that discounts the costs of the projects—that is, the costs at Year 0 and Year 2—at the risk-free rate of 6%; then sum the two decision trees to find the total NPV.)
c. Instead of using decision-tree analysis, use the Black-Scholes model to estimate the value of the growth option. Assume that the variance of the project's rate of return is 0.15. Find the total value of the project with the option to expand—that is, the sum of the original expected value and the growth option. (*Hint:* You will need to find the expected present value of the additional project's operating cash flows in order to estimate the current price of the option's underlying asset.)

PROBLEMS

Answers Are in Appendix B

INTERMEDIATE PROBLEMS 1–5

(26-1) Investment Timing Option: Decision-Tree Analysis

Kim Hotels is interested in developing a new hotel in Seoul. The company estimates that the hotel would require an initial investment of $20 million. Kim expects the hotel will produce positive cash flows of $3 million a year at the end of each of the next 20 years. The project's cost of capital is 13%.

a. What is the project's net present value?
b. Kim expects the cash flows to be $3 million a year, but it recognizes that the cash flows could actually be much higher or lower, depending on whether the Korean government imposes a large hotel tax. One year from now, Kim will know whether the tax will be imposed. There is a 50% chance that the tax will be imposed, in which case the yearly cash flows will be only $2.2 million. At the same time, there is a 50% chance that the tax will not be imposed, in which case the yearly cash flows will be $3.8 million. Kim is deciding whether to proceed with the hotel today or to wait a year to find out whether the tax will be imposed. If Kim waits a year, the initial investment will remain at $20 million. Assume that all cash flows are discounted at 13%. Use decision-tree analysis to determine whether Kim should proceed with the project today or wait a year before deciding.

(26-2) Investment Timing Option: Decision-Tree Analysis

The Karns Oil Company is deciding whether to drill for oil on a tract of land the company owns. The company estimates the project would cost $8 million today. Karns estimates that, once drilled, the oil will generate positive net cash flows of $4 million a year at the end of each of the next 4 years. Although the company is fairly confident about its cash flow forecast, in 2 years it will have more information about the local geology and about the price of oil. Karns estimates that if it waits 2 years then the project would cost $9 million. Moreover, if it waits 2 years, then there is a 90% chance that the net cash flows would be $4.2 million a year for 4 years and a 10% chance that they would be $2.2 million a year for 4 years. Assume all cash flows are discounted at 10%.

a. If the company chooses to drill today, what is the project's net present value?
b. Using decision-tree analysis, does it make sense to wait 2 years before deciding whether to drill?

(26-3) Investment Timing Option: Decision-Tree Analysis

Hart Lumber is considering the purchase of a paper company, which would require an initial investment of $300 million. Hart estimates that the paper company would provide net cash flows of $40 million at the end of each of the next 20 years. The cost of capital for the paper company is 13%.

a. Should Hart purchase the paper company?
b. Hart's best guess is that cash flows will be $40 million a year, but it realizes that the cash flows are as likely to be $30 million a year as $50 million. One year from now, it will find out whether the cash flows will be $30 million or $50 million. In addition, Hart could sell the paper company at Year 3 for $280 million. Given this additional information, does decision-tree analysis indicate that it makes sense to purchase the paper company? Again, assume that all cash flows are discounted at 13%.

(26-4) Real Options: Decision-Tree Analysis

Utah Enterprises is considering buying a vacant lot that sells for $1.2 million. If the property is purchased, the company's plan is to spend another $5 million today $(t = 0)$ to build a hotel on the property. The after-tax cash flows from the hotel will depend critically on whether the state imposes a tourism tax in this year's legislative session. If the tax is imposed, the hotel is expected to produce after-tax cash inflows of $600,000 at the end of each of the next 15 years, versus $1,200,000 if the tax is not imposed. The project has

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

a 12% cost of capital. Assume at the outset that the company does not have the option to delay the project. Use decision-tree analysis to answer the following questions.

a. What is the project's expected NPV if the tax is imposed?
b. What is the project's expected NPV if the tax is not imposed?
c. Given that there is a 50% chance that the tax will be imposed, what is the project's expected NPV if the company proceeds with it today?
d. Although the company does not have an option to delay construction, it does have the option to abandon the project 1 year from now if the tax is imposed. If it abandons the project, it would sell the complete property 1 year from now at an expected price of $6 million. Once the project is abandoned, the company would no longer receive any cash inflows from it. If all cash flows are discounted at 12%, would the existence of this abandonment option affect the company's decision to proceed with the project today?
e. Assume there is no option to abandon or delay the project but that the company has an option to purchase an adjacent property in 1 year at a price of $1.5 million. If the tourism tax is imposed, then the net present value of developing this property (as of t = 1) is only $300,000 (so it wouldn't make sense to purchase the property for $1.5 million). However, if the tax is not imposed, then the net present value of the future opportunities from developing the property would be $4 million (as of t = 1). Thus, under this scenario it would make sense to purchase the property for $1.5 million. Given that cash flows are discounted at 12% and that there's a 50-50 chance the tax will be imposed, how much would the company pay today for the option to purchase this property 1 year from now for $1.5 million?

(26-5) Growth Option: Decision-Tree Analysis

Fethe's Funny Hats is considering selling trademarked, orange-haired curly wigs for University of Tennessee football games. The purchase cost for a 2-year franchise to sell the wigs is $20,000. If demand is good (40% probability), then the net cash flows will be $25,000 per year for 2 years. If demand is bad (60% probability), then the net cash flows will be $5,000 per year for 2 years. Fethe's cost of capital is 10%.

a. What is the expected NPV of the project?
b. If Fethe makes the investment today, then it will have the option to renew the franchise fee for 2 more years at the end of Year 2 for an additional payment of $20,000. In this case, the cash flows that occurred in Years 1 and 2 will be repeated (so if demand was good in Years 1 and 2, it will continue to be good in Years 3 and 4). Write out the decision tree and use decision-tree analysis to calculate the expected NPV of this project, including the option to continue for an additional 2 years. *Note:* The franchise fee payment at the end of Year 2 is known, so it should be discounted at the risk-free rate, which is 6%.

CHALLENGING PROBLEMS 6–8

(26-6) Investment Timing Option: Option Analysis

Rework Problem 26-1 using the Black-Scholes model to estimate the value of the option. Assume that the variance of the project's rate of return is 6.87% and that the risk-free rate is 8%.

(26-7) Investment Timing Option: Option Analysis

Rework Problem 26-2 using the Black-Scholes model to estimate the value of the option. Assume that the variance of the project's rate of return is 0.111 and that the risk-free rate is 6%.

(26-8) Growth Option: Option Analysis

Rework Problem 26-5 using the Black-Scholes model to estimate the value of the option. Assume that the variance of the project's rate of return is 0.2025 and that the risk-free rate is 6%.

SPREADSHEET PROBLEM

(26-9) Build a Model: Real Options

Start with the partial model in the file ***Ch26 P09 Build a Model.xlsx*** on the textbook's Web site. Bradford Services Inc. (BSI) is considering a project with a cost of $10 million and an expected life of 3 years. There is a 30% probability of good conditions, in which case the project will provide a cash flow of $9 million at the end of each of the next 3 years. There is a 40% probability of medium conditions, in which case the annual cash flows will be $4 million, and there is a 30% probability of bad conditions with a cash flow of −$1 million per year. BSI uses a 12% cost of capital to evaluate projects like this.

a. Find the project's expected present value, NPV, and the coefficient of variation of the present value.
b. Now suppose that BSI can abandon the project at the end of the first year by selling it for $6 million. BSI will still receive the Year-1 cash flows, but will receive no cash flows in subsequent years.
c. Now assume that the project cannot be shut down. However, expertise gained by taking it on would lead to an opportunity at the end of Year 3 to undertake a venture that would have the same cost as the original project, and the new project's cash flows would follow whichever branch resulted for the original project. In other words, there would be a second $10 million cost at the end of Year 3 followed by cash flows of either $9 million, $4 million, or −$1 million for the subsequent 3 years. Use decision-tree analysis to estimate the value of the project, including the opportunity to implement the new project at Year 3. Assume that the $10 million cost at Year 3 is known with certainty and should be discounted at the risk-free rate of 6%.
d. Now suppose the original project (no abandonment option or additional growth option) could be delayed a year. All the cash flows would remain unchanged, but information obtained during that year would tell the company exactly which set of demand conditions existed. Use decision-tree analysis to estimate the value of the project if it is delayed by 1 year. (*Hint:* Discount the $10 million cost at the risk-free rate of 6% because the cost is known with certainty.)
e. Go back to part c. Instead of using decision-tree analysis, use the Black-Scholes model to estimate the value of the growth option. The risk-free rate is 6%, and the variance of the project's rate of return is 0.22.

MINI CASE

Assume you have just been hired as a financial analyst by Tropical Sweets Inc., a mid-size California company that specializes in creating exotic candies from tropical fruits such as mangoes, papayas, and dates. The firm's CEO, George Yamaguchi, recently returned from an industry corporate executive conference in San Francisco, and one of the sessions he attended addressed real options. Because no one at Tropical Sweets is familiar with the basics of real options, Yamaguchi has asked you to prepare a brief report that the firm's executives can use to gain a cursory understanding of the topic.

To begin, you gathered some outside materials on the subject and used these materials to draft a list of questions that need to be answered. Now that the questions have been drafted, you must develop the answers.

a. What are some types of real options?
b. What are five possible procedures for analyzing a real option?

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

c. Tropical Sweets is considering a project that will cost $70 million and will generate expected cash flows of $30 million per year for 3 years. The cost of capital for this type of project is 10%, and the risk-free rate is 6%. After discussions with the marketing department, you learn that there is a 30% chance of high demand with associated future cash flows of $45 million per year. There is also a 40% chance of average demand with cash flows of $30 million per year as well as a 30% chance of low demand with cash flows of only $15 million per year. What is the expected NPV?
d. Now suppose this project has an investment timing option, because it can be delayed for a year. The cost will still be $70 million at the end of the year, and the cash flows for the scenarios will still last 3 years. However, Tropical Sweets will know the level of demand and will implement the project only if it adds value to the company. Perform a qualitative assessment of the investment timing option's value.
e. Use decision-tree analysis to calculate the NPV of the project with the investment timing option.
f. Use a financial option pricing model to estimate the value of the investment timing option.
g. Now suppose that the cost of the project is $75 million and the project cannot be delayed. However, if Tropical Sweets implements the project, then the firm will have a growth option: the opportunity to replicate the original project at the end of its life. What is the total expected NPV of the two projects if both are implemented?
h. Tropical Sweets will replicate the original project only if demand is high. Using decision-tree analysis, estimate the value of the project with the growth option.
i. Use a financial option model to estimate the value of the project with the growth option.
j. What happens to the value of the growth option if the variance of the project's return is 0.142? What if it is 0.50? How might this explain the high valuations of many start-up high-tech companies that have yet to show positive earnings?

APPENDIX A

Solutions to Self-Test Problems

CHAPTER 2

ST-1 a.

EBIT	$5,000,000
Interest	1,000,000
EBT	$4,000,000
Taxes 40%	1,600,000
Net income	$2,400,000

b. $$\begin{aligned} \text{NCF} &= \text{NI} + \text{DEP and AMORT} \\ &= \$2{,}400{,}000 + 1{,}000{,}000 = \$3{,}400{,}000 \end{aligned}$$

c. $$\begin{aligned} \text{NOPAT} &= \text{EBIT}(1 - \text{T}) \\ &= \$5{,}000{,}000(0.6) \\ &= \$3{,}000{,}000 \end{aligned}$$

d. $$\begin{aligned} \text{NOWC} &= \text{Operating current assets} - \text{Operating current liabilities} \\ &= (\text{Cash} + \text{Accounts receivable} + \text{Inventory}) \\ &\quad -(\text{Accounts payable} + \text{Accruals}) \\ &= \$14{,}000{,}000 - \$4{,}000{,}000 \\ &= \$10{,}000{,}000 \end{aligned}$$

$$\begin{aligned} \text{Total net operating capital} &= \text{NOWC} + \text{Operating long-term assets} \\ &= \$10{,}000{,}000 + \$15{,}000{,}000 \\ &= \$25{,}000{,}000 \end{aligned}$$

e. $$\begin{aligned} \text{FCF} &= \text{NOPAT} - \text{Net investment in operating capital} \\ &= \$3{,}000{,}000 - (\$25{,}000{,}000 - \$24{,}000{,}000) \\ &= \$2{,}000{,}000 \end{aligned}$$

f. $$\begin{aligned} \text{ROIC} &= \text{NOPAT}/\text{Total net operating capital} \\ &= \$3{,}000{,}000/\$25{,}000{,}000 \\ &= 12\% \end{aligned}$$

g. $$\begin{aligned} \text{EVA} &= \text{NOPAT} - (\text{Total net operating capital})(\text{After-tax cost of capital}) \\ &= \$5{,}000{,}000(0.6) - (\$25{,}000{,}000)(0.10) \\ &= \$3{,}000{,}000 - \$2{,}500{,}000 = \$500{,}000 \end{aligned}$$

CHAPTER 3

ST-1 Argent has $120 million in debt. With $150 million in total liabilities and $210 million in total common equity, Argent has $150 + $210 = $360 million in total liabilities and equity. Therefore, Argent also has $360 million in total assets (because balance sheets must balance). Argent's debt-to-assets ratio is:

$$\text{Debt-to-assets} = \frac{\text{Total debt}}{\text{Total assets}} = \frac{\$120}{\$360} = 33.33\%$$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Argent's debt-to-equity ratio is:

$$\text{Debt-to-equity} = \frac{\text{Total debt}}{\text{Total common equity}} = \frac{\$120}{\$210} = 57.14\%$$

ST-2 a. In answering questions such as this, always begin by writing down the relevant definitional equations and then start filling in numbers. *Note:* All dollar values are in millions.

(1) $$\text{DSO} = \frac{\text{Accounts receivable}}{\text{Sales}/365}$$

$$40 = \frac{\text{AR}}{\text{Sales}/365}$$

$$\text{AR} = 40(\$14{,}600/365) = \$1{,}600$$

(2) $$\text{Quick ratio} = \frac{\text{Current assets} - \text{Inventories}}{\text{Current liabilities}} = 2.0$$

$$\text{Quick ratio} = \frac{\text{Cash} + \text{AR}}{\text{Current liabilities}} = 2.0$$

$$\text{Current liabilities} = \frac{\text{Cash} + \text{AR}}{\text{Quick ratio}}$$

$$\text{Current liabilities} = (\$400 + \$1{,}600)/2 = \$1{,}000$$

(3) $$\text{Current ratio} = \frac{\text{Current assets}}{\text{Current liabilities}} = 3.0$$

$$\text{Current assets} = (\text{Current ratio})(\text{Current liabilities})$$

$$\text{Current assets} = 3.0(\$1{,}000) = \$3{,}000$$

(4) $$\text{Total assets} = \text{Current assets} + \text{Fixed assets}$$

$$= \$3{,}000 + \$4{,}300 = \$7{,}300$$

(5) $$\text{ROA} = \frac{\text{Net income}}{\text{Total assets}}$$

$$\text{ROA} = \frac{\$730}{\$7{,}300} = 0.10 = 10\%$$

(6) $$\text{ROE} = \frac{\text{Net income}}{\text{Equity}} = 12.5\%$$

$$\text{Equity} = \frac{\text{Net income}}{\text{ROE}}$$

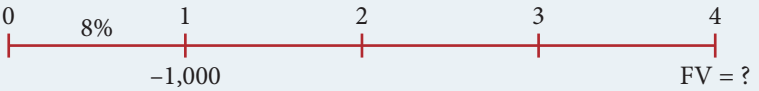
$$\text{Equity} = \$730/0.125 = \$5{,}840 \text{ million}$$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(7) Total assets = Total claims = \$7,300
Total assets = Current liabilities + Long-term debt + Equity
Long-term debt = Total assets − Current liabilities − Equity
Long-term debt = \$7,300 − \$1,000 − \$5,840 = \$460

(8) $$\text{Equity multiplier} = \frac{\text{Total assets}}{\text{Equity}} = \frac{\$7,300}{\$5,840} = 1.25$$

(9) $$\text{Profit margin} = \frac{\text{Net income}}{\text{Sales}} = \frac{\$730}{\$14,600} = 0.05 = 5\%$$



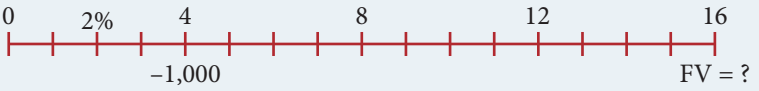
(10) $$\text{Total asset turnover} = \frac{\text{Sales}}{\text{Total assets}} = \frac{\$14,600}{\$7,300} = 2$$

The DuPont equation is:

ROE = (Profit margin)(Total assets turnover)(Equity multiplier)
ROE = (5%)(1.25)(2)
= \$12.5%

CHAPTER 4

ST-1 a.

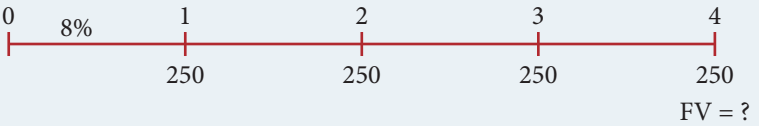


\$1,000 is being compounded for 3 years, so your balance at Year 4 is \$1,259.71:

$$FV_N = PV(1 + I)^N = \$1,000(1 + 0.08)^3 = \$1,259.71$$

Alternatively, using a financial calculator, input N = 3, I/YR = 8, PV = −1000, and PMT = 0; then solve for FV = \$1,259.71.

b.

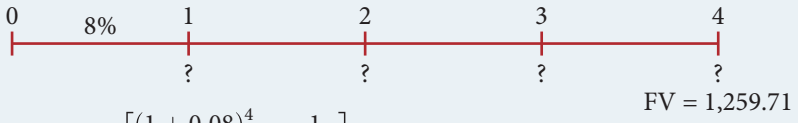


There are 12 compounding periods from Quarter 4 to Quarter 16.

$$FV_N = PV\left(1 + \frac{I_{NOM}}{M}\right)^{NM} = FV_{12} = \$1,000(1.02)^{12} = \$1,268.24$$

Alternatively, using a financial calculator, input N = 12, I/YR = 2, PV = −1000, and PMT = 0; then solve for FV = \$1,268.24.

c.

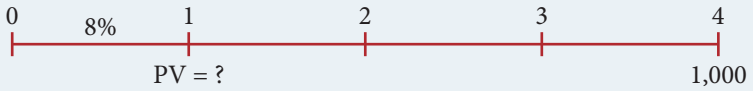


$$FVA_4 = \$250\left[\frac{(1 + 0.08)^4}{0.08} - \frac{1}{0.08}\right] = \$1,126.53$$

Using a financial calculator, input N = 4, I/YR = 8, PV = 0, and PMT = −250; then solve for FV = \$1,126.53.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

d.



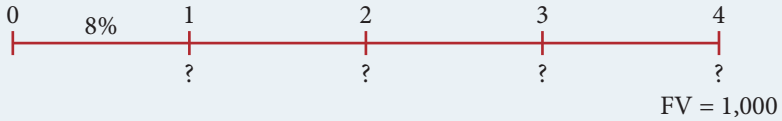
$$\text{PMT}\left[\frac{(1+0.08)^4}{0.08} - \frac{1}{0.08}\right] = \$1{,}259.71$$

$$\text{PMT}(4.5061) = \$1{,}259.71$$

$$\text{PMT} = \$279.56$$

Using a financial calculator, input N = 4, I/YR = 8, PV = 0, and FV = 1259.71; then solve for PMT = −$279.56.

ST-2 a. Set up a time line like the one in the preceding problem:



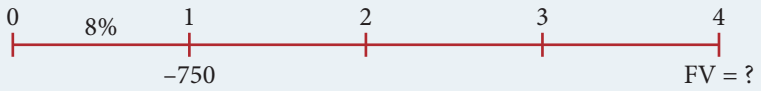
Note that your deposit will grow for 3 years at 8%. The deposit at Year 1 is the PV, and the FV is $1,000. Here is the solution:

N = 3, I/YR = 8, PMT = 0, FV = 1000; then PV = $793.83

Alternatively,

$$\text{PV} = \frac{\text{FV}_N}{(1+\text{I})^N} = \frac{\$1{,}000}{(1+0.08)^3} = \$793.83$$

b.



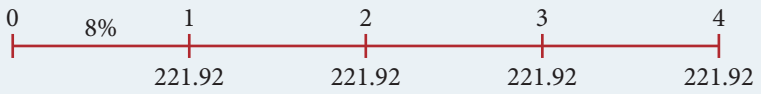
Here we are dealing with a 4-year annuity whose first payment occurs 1 year from today and whose future value must equal $1,000. Here is the solution: N = 4, I/YR = 8, PV = 0, FV = 1000; then PMT = $221.92. Alternatively,

$$\text{PMT}\left[\frac{(1+0.08)^4}{0.08} - \frac{1}{0.08}\right] = \$1{,}000$$

$$\text{PMT}(4.5061) = \$1{,}000$$

$$\text{PMT} = \$221.92$$

c. This problem can be approached in several ways. Perhaps the simplest is to ask this question: "If I received $750 1 year from now and deposited it to earn 8%, would I have the required $1,000 4 years from now?" The answer is "no":

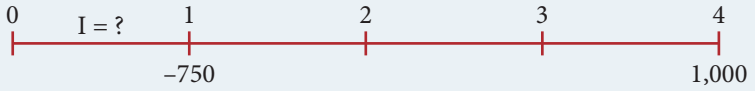


$$\text{FV}_3 = \$750(1.08)(1.08)(1.08) = \$944.78$$

This indicates that you should let your father make the payments rather than accept the lump sum of $750.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

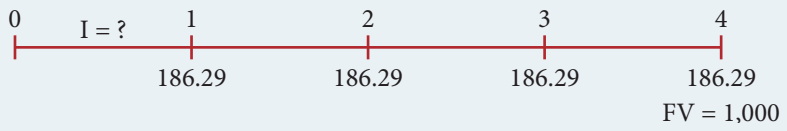
You could also compare the $750 with the PV of the payments:



$$N = 4, I/YR = 8, PMT = -221.92, FV = 0; \text{ then } PV = \$735.03$$

Alternatively,

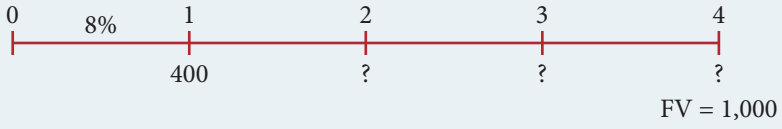
$$PVA_4 = \$221.92\left[\frac{1}{0.08} - \frac{1}{(0.08)(1+0.08)^4}\right] = \$735.03$$



This is less than the $750 lump sum offer, so your initial reaction might be to accept the lump sum of $750. However, it would be a mistake to do so. The problem is that, when you found the $735.03 PV of the annuity, you were finding the value of the annuity *today*. You were comparing $735.03 today with the lump sum of $750 in 1 year. This is, of course, invalid. What you should have done was take the $735.03, recognize that this is the PV of an annuity as of today, multiply $735.03 by 1.08 to get $793.83, and compare this $793.83 with the lump sum of $750. You would then take your father's offer to make the payments rather than take the lump sum 1 year from now.

d.

$$N = 3, PV = -750, PMT = 0, FV = 1000; \text{ then } I/YR = 10.0642\%$$



e.

$$N = 4, PV = 0, PMT = -186.29, FV = 1000; \text{ then } I/YR = 19.9997\%$$

You might be able to find a borrower willing to offer you a 20% interest rate, but there would be some risk involved—he or she might not actually pay you your $1,000!

f.

Find the future value of the original $400 deposit:

$$FV_6 = PV(1+I)^6 = 400(1+0.04)^6 = \$400(1.2653) = \$506.12$$

This means that, at Year 4, you need an additional sum of $493.88: $\$1,000.00 - \$506.12 = \$493.88$. This amount will be accumulated by making 6 equal payments that earn 8% compounded semiannually, or 4%

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

each 6 months: N = 6, I/YR = 4, PV = 0, FV = 493.88; then PMT = $74.46. Alternatively,

$$\text{PMT}\left[\frac{(1+0.04)^6}{0.04}-\frac{1}{0.04}\right] = \$493.88$$

$$\text{PMT}(6.6330) = \$493.88$$

$$\text{PMT} = \$74.46$$

g.
$$\text{EFF\%} = \left(1+\frac{I_{NOM}}{M}\right)^M - 1.0$$

$$= \left(1+\frac{0.08}{2}\right)^2 - 1.0$$

$$= 1.0816 - 1 = 0.0816 = 8.16\%$$

ST-3 Bank A's effective annual rate is 8.24%:

$$\text{EFF\%} = \left(1+\frac{0.08}{4}\right)^4 - 1.0$$

$$= 1.0824 - 1 = 0.0824 = 8.24\%$$

Now Bank B must have the same effective annual rate:

$$\left(1+\frac{I}{12}\right)^{12} - 1.0 = 0.0824$$

$$\left(1+\frac{I}{12}\right)^{12} = 1.0824$$

$$1+\frac{I}{12} = (1.0824)^{1/12}$$

$$1+\frac{I}{12} = 1.00662$$

$$\frac{I}{12} = 0.00662$$

$$I = 0.07944 = 7.94\%$$

Thus, the two banks have different quoted rates—Bank A's quoted rate is 8%, whereas Bank B's quoted rate is 7.94%—yet both banks have the same effective annual rate of 8.24%. The difference in their quoted rates is due to the difference in compounding frequency.

CHAPTER 5

ST-1 a. Pennington's bonds were sold at par; therefore, the original YTM equaled the coupon rate of 12%.

b.
$$V_B = \sum_{t=1}^{50}\frac{\$120/2}{\left(1+\frac{0.10}{2}\right)^t} + \frac{\$1,000}{\left(1+\frac{1.10}{2}\right)^{50}}$$

$$= \$60\left[\frac{1}{0.05}-\frac{1}{0.05(1+0.05)^{50}}\right] + \frac{\$1,000}{(1+0.05)^{50}}$$

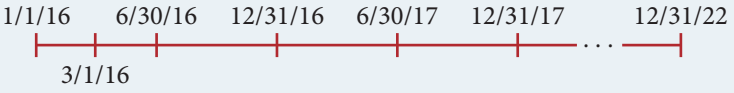
$$= \$1,182.56$$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Alternatively, with a financial calculator, input the following: N = 50, I/YR = 5, PMT = 60, and FV = 1000; solve for PV = −$1,182.56.

c.
$$\begin{aligned}\text{Current yield} &= \text{Annual coupon payment} \div \text{Price}\\ &= \$120/\$1{,}182.56\\ &= 0.1015 = 10.15\%\end{aligned}$$

$$\begin{aligned}\text{Capital gains yield} &= \text{Total yield} - \text{Current yield}\\ &= 10\% - 10.15\% = -0.15\%\end{aligned}$$



$$\begin{aligned}\text{Total yield} &= \text{Current yield} + \text{Capital gains yield}\\ &= 10.15\% + (-0.15\%) = 10.00\%\end{aligned}$$

d.
$$\$916.42 = \sum_{t=1}^{13} \frac{\$60}{(1 + r_d/2)^t} + \frac{\$1000}{(1 + r_d/2)^{13}}$$

With a financial calculator, input the following: N = 13, PV = −916.42, PMT = 60, and FV = 1000; then solve for = I/YR = $r_d/2$ = 7.00%. Therefore, r_d = 14.00%.

$$\begin{aligned}\text{Current yield} &= \$120/\$916.42 = 13.09\%\\ \text{Capital gains yield} &= 14\% - 13.09\% = \underline{\ 0.91\%}\\ \text{Total yield} &= 14.00\%\end{aligned}$$

e. The following time line illustrates the years to maturity of the bond:

Thus, on March 1, 2016, there were 13⅔ periods left before the bond matured. Bond traders actually use the following procedure to determine the price of the bond.

(1) Find the price of the bond immediately after the next coupon is paid on June 30, 2016:

$$\begin{aligned}V_B &= \$60\left[\frac{1}{0.0775} - \frac{1}{0.0775(1 + 0.0775)^{13}}\right] + \frac{\$1{,}000}{(1 + 0.0775)^{13}}\\ &= \$859.76\end{aligned}$$

Using a financial calculator, input N = 13, I/YR = 7.75, PMT = 60, and FV = 1000; then solve for PV = −$859.76.

(2) Add the coupon, $60, to the bond price to get the total value, TV, of the bond on the next interest payment date: TV = $859.76 + $60.00 = $919.76.

(3) Discount this total value back to the purchase date:

$$\begin{aligned}\text{Value at purchase date (March 1, 2016)} &= \frac{\$919.76}{(1 + 0.0775)^{(4/6)}}\\ &= \$875.11\end{aligned}$$

Using a financial calculator, input N = 4/6, I/YR = 7.75, PMT = 0, and FV = 919.76; then solve for PV = $875.11.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(4) Therefore, you would have written a check for \$875.11 to complete the transaction. Of this amount, \$20 = (⅓)(\$60) would represent accrued interest and \$855.11 would represent the bond's basic value. This breakdown would affect both your taxes and those of the seller.

(5) This problem could be solved *very* easily using a spreadsheet or a financial calculator with a bond valuation function.

CHAPTER 6

ST-1

a. The average rate of return for each stock is calculated simply by averaging the returns over the 5-year period. The average return for Stock A is:

$$\begin{aligned} r_{Avg\ A} &= (-18\% + 44\% - 22\% + 22\% + 34\%)/5 \\ &= 12\% \end{aligned}$$

The realized rate of return on a portfolio made up of Stock A and Stock B would be calculated by finding the average return in each year as:

$$r_A(\%\text{ of Stock A}) + r_B(\%\text{ of Stock B})$$

and then averaging these annual returns:

Year	Portfolio AB's Return, r_{AB}
2012	−21%
2013	34
2014	−13
2015	15
2016	45
	r_{Avg} = 12%

b. The standard deviation of returns is estimated as follows:

$$\text{Estimated } \sigma = S = \sqrt{\frac{\sum_{t=1}^{N} (\bar{r}_t - \bar{r}_{Avg})^2}{N-1}}$$

For Stock A, the estimated σ is about 30%:

$$\begin{aligned} \sigma_A &= \sqrt{\frac{(-0.18 - 0.12)^2 + (0.44 - 0.12)^2 + (-0.22 - 0.12)^2 + (0.22 - 0.12)^2 + (0.34 - 0.12)^2}{5 - 1}} \\ &= 0.30265 \approx 30\% \end{aligned}$$

The standard deviations of returns for Stock B and for the portfolio are similarly determined, and they are as follows:

	Stock A	Stock B	Portfolio AB
Standard deviation	30%	30%	29%

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

c. Because the risk reduction from diversification is small (σ_{AB} falls only from 30% to 29%), the most likely value of the correlation coefficient is 0.8. If the correlation coefficient were −0.8, then the risk reduction would be much larger. In fact, the correlation coefficient between Stocks A and B is 0.8.

d. If more randomly selected stocks were added to a portfolio, σ_P would decline to somewhere in the vicinity of 20%. The value of σ_P would remain constant only if the correlation coefficient were +1.0, which is most unlikely. The value of σ_P would decline to zero only if $\rho = -1.0$ for some pair of stocks or some pair of portfolios.

ST-2

a. $$\begin{aligned} b &= (0.6)(0.70) + (0.25)(0.90) + (0.1)(1.30) + (0.05)(1.50) \\ &= 0.42 + 0.225 + 0.13 + 0.075 = 0.85 \end{aligned}$$

b. $$\begin{aligned} r_{RF} &= 6\%; RP_M = 5\%; b = 0.85 \\ r_P &= 6\% + (5\%)(0.85) \\ &= 10.25\% \end{aligned}$$

c. $$\begin{aligned} b_N &= (0.5)(0.70) + (0.25)(0.90) + (0.1)(1.30) + (0.15)(1.50) \\ &= 0.35 + 0.225 + 0.13 + 0.225 \\ &= 0.93 \\ r &= 6\% + (5\%)(0.93) \\ &= 10.65\% \end{aligned}$$

CHAPTER 7

ST-1

The first step is to solve for g_L, the unknown variable, in the constant growth equation. Because D_1 is unknown but D_0 is known, substitute $D_0(1 + g_L)$ as follows:

$$\hat{P}_0 = P_0 = \frac{D_1}{r_s - g_L} = \frac{D_0(1 + g_L)}{r_s - g_L}$$

$$\$36 = \frac{\$2.40(1 + g_L)}{0.12 - g_L}$$

Solving for g_L, we find the growth rate to be 5%:

$$\begin{aligned} \$4.32 - \$36g_L &= \$2.40 + \$2.40g_L \\ \$38.4g_L &= \$1.92 \\ g_L &= 0.05 = 5\% \end{aligned}$$

The next step is to use the growth rate to project the stock price 5 years hence:

$$\begin{aligned} \hat{P}_5 &= \frac{D_0(1 + g_L)^6}{r_s - g_L} \\ &= \frac{\$2.40(1.05)^6}{0.12 - 0.05} \\ &= \$45.95 \end{aligned}$$

(Alternatively, $\hat{P}_5 = \$36(1.05)^5 = \$45.95$.) Therefore, Ewald Company's expected stock price 5 years from now, $\hat{P}_5$, is $45.95.

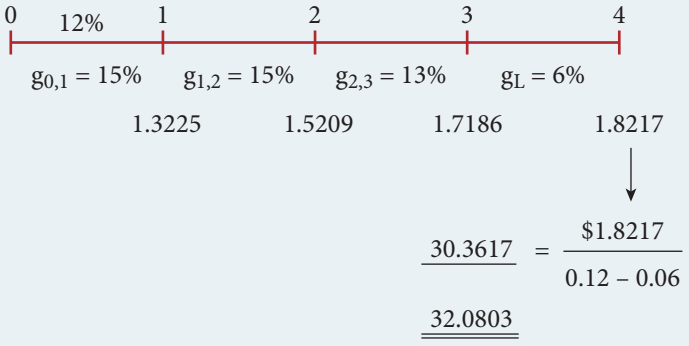
ST-2

a. (1) Calculate the PV of the dividends paid during the supernormal growth period:

$$\begin{aligned} D_1 &= \$1.1500(1.15) = \$1.3225 \\ D_2 &= \$1.3225(1.15) = \$1.5209 \\ D_3 &= \$1.5209(1.13) = \$1.7186 \end{aligned}$$

$$\begin{aligned} \text{PV of Div.} &= \$1.3225/(1.12) + \$1.5209/(1.12)^2 + \$1.7186/(1.12)^3 \\ &= \$3.6167 \approx \$3.62 \end{aligned}$$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.



(2) Find the PV of Snyder's stock price at the end of Year 3:

$$\hat{P}_3 = \frac{D_4}{r_s - g_L} = \frac{D_3(1 + g_L)}{r_s - g_L}$$
$$= \frac{\$1.7186(1.06)}{0.12 - 0.06}$$
$$= \$30.36$$
$$\text{PV of } \hat{P}_3 = 30.36/(1.12)^3 = 21.61$$

(3) Sum the two components to find the value of the stock today:

$$\hat{P}_0 = \$3.62 + \$21.61 = \$25.23$$

Alternatively, the cash flows can be placed on a time line as follows:

Enter the cash flows into the cash flow register ($CF_0 = 0$, $CF_1 = 1.3225$, $CF_2 = 1.5209$, $CF_3 = 32.0803$) and I/YR = 12; then press the NPV key to obtain $\hat{P}_0 = \$25.23$.

b. $$\hat{P}_1 = \$1.5209/(1.12) + \$1.7186/(1.12)^2 + \$30.36/(1.12)^2$$
$$= \$26.9311 \approx \$26.93$$
(Calculator solution: $26.93)

$$\hat{P}_2 = \$1.7186/(1.12) + \$30.36/(1.12)$$
$$= \$28.6429 \approx \$28.64$$
(Calculator solution: $28.64)

c.

Year	Dividend Yield	+	Capital Gains Yield	=	Total Return
1	$\frac{\$1.3225}{\$25.23} \approx 5.24\%$	+	$\frac{\$29.93 - \$25.23}{\$25.23} \approx 6.74\%$	≈	12%
2	$\frac{\$1.5209}{\$26.93} \approx 5.65\%$	+	$\frac{\$28.64 - \$26.93}{\$26.93} \approx 6.35\%$	≈	12%
3	$\frac{\$1.7186}{\$28.64} \approx 6.00\%$	+	$\frac{\$30.36 - \$28.64}{\$28.64} \approx 6.00\%$	≈	12%

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

ST-3 a. $$V_{op} = \frac{FCF(1+g)}{WACC - g} = \frac{\$100{,}000(1+0.07)}{0.11 - 0.07} = \$2{,}675{,}000$$

b. $$\begin{aligned}\text{Total value} &= \text{Value of operations} + \text{Value of nonoperating assets}\\ &= \$2{,}675{,}000 + \$325{,}000 = \$3{,}000{,}000\end{aligned}$$

c. $$\begin{aligned}\text{Value of equity} &= \text{Total value} - \text{Value of debt}\\ &= \$3{,}000{,}000 - \$1{,}000{,}000 = \$2{,}000{,}000\end{aligned}$$

d. $$\begin{aligned}\text{Price per share} &= \text{Value of equity} \div \text{Number of shares}\\ &= \$2{,}000{,}000/50{,}000 = \$40\end{aligned}$$

CHAPTER 8

ST-1 The option will pay off \$60 − \$42 = \$18 if the stock price is up. The option pays off nothing (\$0) if the stock price is down. Find the number of shares in the hedge portfolio:

$$N = \frac{C_u - C_d}{P_u - P_d} = \frac{\$18 - \$0}{\$60 - \$30} = 0.60$$

With 0.6 shares, the stock's payoff will be either $0.6(\$60) = \$36$ or $0.6(\$30) = \$18$. The portfolio's payoff will be \$36 − \$18 = \$18, or \$18 − 0 = \$18.

The present value of \$18 at the daily compounded risk-free rate is $PV = \$18/[1 + (0.05/365)]^{365} = \$17.12$. Or use a financial calculator and enter N = 365, I/YR = 5/365, PMT = 0, and FV = −18; solve for PV = 17.12. The option price is the current value of the stock in the portfolio minus the PV of the payoff:

$$V = 0.6(\$40) - \$17.12 = \$6.88$$

ST-2

$$\begin{aligned}d_1 &= \frac{\ln(P/X) + [r_{RF} + (\sigma^2/2)]t}{\sigma\sqrt{t}}\\ &= \frac{\ln(\$22/\$20) + [0.05 + (0.49/2)](0.5)}{0.7\sqrt{0.5}}\\ &= 0.4906\end{aligned}$$

$$d_2 = d_1 - \sigma(t)^{0.5} = 0.4906 - 0.7(0.5)^{0.5} = -0.0044$$

$$N(d_1) = 0.6881 \text{(from } \textit{Excel} \text{ NORMSDIST function)}$$

$$N(d_2) = 0.4982 \text{(from } \textit{Excel} \text{ NORMSDIST function)}$$

$$\begin{aligned}V &= P[N(d_1)] - Xe^{-r_{RF}t}[N(d_2)]\\ &= \$22(0.6881) - \$20e^{(-0.05)(0.5)}(0.4982)\\ &= \$5.42\end{aligned}$$

CHAPTER 9

ST-1 a. Component costs are as follows:

Debt at r_d = 9%:

$$r_d(1 - T) = 9\%(0.6) = 5.4\%$$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Preferred with F = 5%:

$$r_{ps} = \frac{\text{Preferred dividend}}{P_{ps}(1 - F)} = \frac{\$9}{\$100(0.95)} = 9.5\%$$

Common with dividend growth approach:

$$r_s = \frac{D_1}{P_0} + g_{0,1} = \frac{\$3.922}{\$60} + 6\% = 12.5\%$$

Common with CAPM:

$$r_s = 6\% + 1.3(5\%) = 12.5\%$$

b. $$\begin{aligned} \text{WACC} &= w_d r_d(1 - T) + w_{ps} r_{ps} + w_s r_s \\ &= 0.25(9\%)(1 - T) + 0.15(9.5\%) + 0.60(12.5\%) \\ &= 10.275\% \end{aligned}$$

CHAPTER 10

ST-1 a. **Payback:**

To determine the payback, construct the cumulative cash flows for each project as follows.

	Cumulative Cash Flows	
Year	**Project X**	**Project Y**
0	−$10,000	−$10,000
1	−3,500	−6,500
2	−500	−3,000
3	2,500	500
4	3,500	4,000

$$\text{Payback}_X = 2 + \frac{\$500}{\$3,000} = 2.17 \text{ years}$$

$$\text{Payback}_Y = 2 + \frac{\$3,000}{\$3,500} = 2.86 \text{ years}$$

Net present value (NPV):

$$\text{NPV}_X = -\$10,000 + \frac{\$6,500}{(1.12)^1} + \frac{\$3,000}{(1.12)^2} + \frac{\$3,000}{(1.12)^3} + \frac{\$1,000}{(1.12)^4} = \$966.01$$

$$\text{NPV}_Y = -\$10,000 + \frac{\$3,500}{(1.12)^1} + \frac{\$3,500}{(1.12)^2} + \frac{\$3,500}{(1.12)^3} + \frac{\$3,500}{(1.12)^4} = \$630.72$$

Alternatively, using a financial calculator, input the cash flows into the cash flow register, enter I/YR = 12, and then press the NPV key to obtain $\text{NPV}_X = \$966.01$ and $\text{NPV}_Y = \$630.72$.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Internal rate of return (IRR):

To solve for each project's IRR, find the discount rates that equate each NPV to zero:

$$IRR_X = 18.0\%$$
$$IRR_Y = 15.0\%$$

Modified Internal Rate of Return (MIRR):

To obtain each project's MIRR, begin by finding each project's terminal value (TV) of cash inflows:

$$TV_X = \$6{,}500(1.12)^3 + \$3{,}000(1.12)^2 + \$3{,}000(1.12)^1 + \$1{,}000 = \$17{,}255.23$$
$$TV_Y = \$3{,}500(1.12)^3 + \$3{,}500(1.12)^2 + \$3{,}500(1.12)^1 + \$3{,}500 = \$16{,}727.65$$

Now, each project's MIRR is the discount rate that equates the PV of the TV to each project's cost, $10,000:

$$MIRR_X = 14.61\%$$
$$MIRR_Y = 13.73\%$$

Profitability index (PI):

To obtain each project's PI, divide its present value of future cash flows by its initial cost. The PV of future cash flows can be found from the NPV calculated earlier:

$$PV_X = NPV_X + \text{Cost of X} = \$966.01 + \$10{,}000 = \$10{,}966.01$$
$$PV_Y = NPV_Y + \text{Cost of Y} = \$630.72 + \$10{,}000 = \$10{,}630.72$$
$$PI_X = PV_X/\text{Cost of X} = \$10{,}966.01/\$10{,}000 = 1.097$$
$$PI_Y = PV_Y/\text{Cost of Y} = \$10{,}630.72/\$10{,}000 = 1.063$$

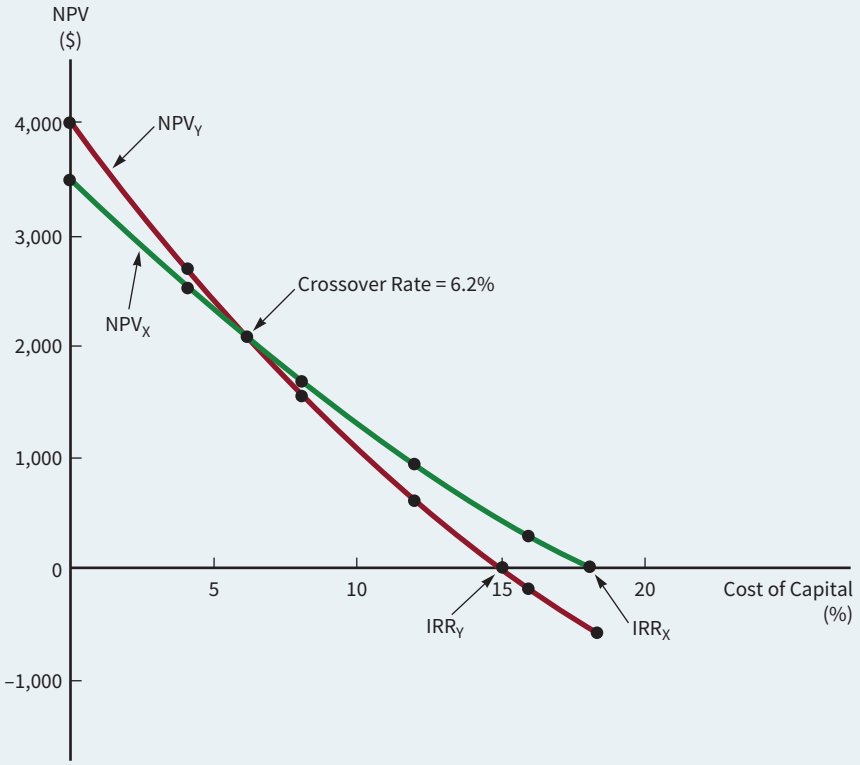
b. The following table summarizes the project rankings by each method:

	Project That Ranks Higher
Payback	X
NPV	X
IRR	X
MIRR	X

Note that all methods rank Project X over Project Y. Because both projects are acceptable under the NPV, IRR, and MIRR criteria, both should be accepted if they are independent.

c. In this case, we would choose the project with the higher NPV at r = 12%, or Project X.

d. To determine the effects of changing the cost of capital, plot the NPV profiles of each project. The crossover rate occurs at about 6% to 7% (6.2%). See the graph following Part e.



If the firm's cost of capital is less than 6.2%, then a conflict exists because $NPV_Y > NPV_X$ but $IRR_X > IRR_Y$. Therefore, if r were 5%, then a conflict would exist. Note, however, that when r = 5.0%, we have $MIRR_X = 10.64\%$ and $MIRR_Y = 10.83\%$; hence, the modified IRR ranks the projects correctly even if r is to the left of the crossover point.

e. The basic cause of the conflict is differing reinvestment rate assumptions between NPV and IRR: NPV assumes that cash flows can be reinvested at

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

the cost of capital, whereas IRR assumes that reinvestment yields the (generally) higher IRR. The high reinvestment rate assumption under IRR makes early cash flows especially valuable, so short-term projects look better under IRR.

NPV Profiles for Projects X and Y

Cost of Capital	NPV_X	NPV_Y
0%	$3,500	$4,000
4	2,545	2,705
8	1,707	1,592
12	966	631
16	307	(206)
18	5	(585)

CHAPTER 11

ST-1 a. **Estimated Investment Requirements:**

Price	−$50,000
Modification	−10,000
Change in net working capital	−2,000
Total investment	−$62,000

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

b. **Operating Cash Flows:**

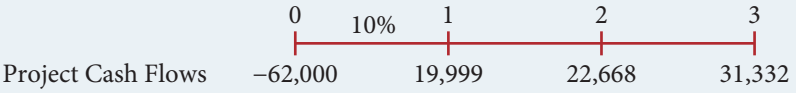
	Year 1	Year 2	Year 3
1. After-tax cost savings[a]	$12,000	$12,000	$12,000
2. Depreciation[b]	19,998	26,670	8,886
3. Depreciation tax savings[c]	7,999	10,668	3,554
Operating cash flow (1 + 3)	$19,999	$22,668	$15,554

[a] $20,000(1 − T).

[b] Depreciable basis = $60,000; the MACRS percentage allowances are 0.3333, 0.4445, and 0.1481 in Years 1, 2, and 3, respectively; hence, depreciation in Year 1 = 0.3333($60,000) = $19,998, Year 2 = 0.4445 ($60,000) = $26,670, and Year 3 = 0.1481 ($60,000) = $8,886. There will remain $4,446, or 7.41%, undepreciated after Year 3; it would normally be taken in Year 4.

[c] Depreciation tax savings = T(Depreciation) = 0.4($19,998) = $7,999.2 in Year 1, and so forth.

c. **Termination Cash Flow:**



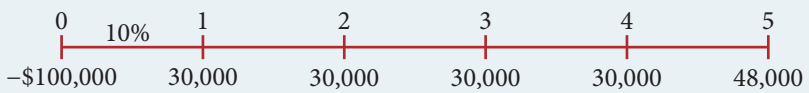
Salvage value	$20,000
Tax on salvage value[a]	−6,222
Net working capital recovery	2,000
Termination cash flow	$15,778

[a] Calculation of tax on salvage value: Calculation of tax on salvage value:

Book value = Depreciation basis − Accumulated depreciation Book value
= $60,000 − $55,554 = $4,446

Sales price	$20,000
Less book value	4,446
Taxable income	$15,554
Tax at 40%	$ 6,222

d. **Project NPV:**

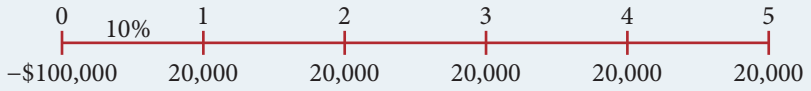


$$NPV = -\$62{,}000 + \frac{\$19{,}999}{(1.10)^1} + \frac{\$22{,}668}{(1.10)^2} + \frac{\$31{,}332}{(1.10)^3}$$
$$= -\$1{,}545$$

Alternatively, using a financial calculator, input the cash flows into the cash flow register, enter I/YR = 10, and then press the NPV key to obtain NPV = −$1,545. Because the earth mover has a negative NPV, it should not be purchased. We rounded all cash flows to integers. If you use *Excel* and do not round, you should get $1,544.23.

ST-2 a. First, find the expected cash flows:

Year	Expected Cash Flows				
0	0.2(−$100,000)	+ 0.6(−$100,000)	+ 0.2(−$100,000)	=	−$100,000
1	0.2($20,000)	+ 0.6($30,000)	+ 0.2($40,000)	=	$30,000
2	0.2($20,000)	+ 0.6($30,000)	+ 0.2($40,000)	=	$30,000
3	0.2($20,000)	+ 0.6($30,000)	+ 0.2($40,000)	=	$30,000
4	0.2($20,000)	+ 0.6($30,000)	+ 0.2($40,000)	=	$30,000
5	0.2($20,000)	+ 0.6($30,000)	+ 0.2($40,000)	=	$30,000
5*	0.2($0)	+ 0.6($20,000)	+ 0.2($30,000)	=	$18,000



Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Next, determine the NPV based on the expected cash flows:

$$\text{NPV} = \$100{,}000 + \frac{\$30{,}000}{(1.10)^1} + \frac{\$30{,}000}{(1.10)^2} + \frac{\$30{,}000}{(1.10)^3} + \frac{\$30{,}000}{(1.10)^4} + \frac{\$48{,}000}{(1.10)^5} = \$24{,}900$$

Alternatively, using a financial calculator, input the cash flows in the cash flow register, enter I/YR = 10, and then press the NPV key to obtain NPV = $24,900.

b. For the worst case, the cash flow values from the cash flow column farthest on the left are used to calculate NPV:

$$\text{NPV} = -\$100{,}000 + \frac{\$20{,}000}{(1.10)^1} + \frac{\$20{,}000}{(1.10)^2} + \frac{\$20{,}000}{(1.10)^3} + \frac{\$20{,}000}{(1.10)^4} + \frac{\$20{,}000}{(1.10)^5} = -\$24{,}184$$

Similarly, for the best case, use the values from the column farthest on the right. Here the NPV is $70,259.

If the cash flows are perfectly dependent, then the low cash flow in the first year will mean a low cash flow in every year. Thus, the probability of the worst case occurring is the probability of getting the $20,000 net cash flow in Year 1, or 20%. If the cash flows are independent, then the cash flow in each year can be low, high, or average and so the probability of getting all low cash flows will be

$$(0.2)(0.2)(0.2)(0.2)(0.2) = 0.2^5 = 0.00032 = 0.032\%$$

c. The base-case NPV is found using the most likely cash flows and is equal to $26,142. This value differs from the expected NPV of $24,900 because the Year-5 cash flows are not symmetric. Under these conditions, the NPV distribution is as follows:

P	NPV
0.2	−$24,184
0.6	26,142
0.2	70,259

Thus, the expected NPV is 0.2 (−$24,184) + 0.6 ($26,142) + 0.2 ($70,259) = $24,900. As is always the case, the expected NPV is the same as the NPV of the expected cash flows found in Part a. The standard deviation is $29,904:

$$\begin{aligned}\sigma^2_{\text{NPV}} &= 0.2(-\$24{,}184 - \$24{,}900)^2 + 0.6(\$26{,}142 - \$24{,}900)^2 \\ &\quad + 0.2(\$70{,}259 - \$24{,}900)^2 \\ &= \$894{,}261{,}126\end{aligned}$$

$$\sigma_{\text{NPV}} = \sqrt{\$894{,}261{,}126} = \$29{,}904$$

The coefficient of variation, CV, is $29,904/$24,900 = 1.20.

CHAPTER 12

ST-1 To solve this problem, we first define ⊠S as the change in sales and g as the growth rate in sales. Then we use the three following equations:

$$\begin{aligned} \boxtimes S &= S_0 g \\ S_1 &= S_0(1+g) \\ AFN &= (A^*/S_0)(\boxtimes S) - (L^*/S_0)(\boxtimes S) - MS_1(1 - \text{Payout ratio}) \end{aligned}$$

Set AFN = 0; substitute in known values for A^*/S_0, L^*/S_0, M, d, and S_0; and then solve for g:

$$\begin{aligned} 0 &= 1.6(\$100g) - 0.4(\$100g) - 0.10[\$100(1+g)](0.55) \\ &= \$160g - \$40g - 0.055(\$100 + \$100g) \\ &= \$160g - \$40g - \$5.5 - \$5.5g \\ \$114.5g &= \$5.5 \\ g &= \$5.5/\$114.5 = 0.048 = 4.8\% \\ &= \text{Maximum growth rate without external financing} \end{aligned}$$

ST-2 Assets consist of cash, marketable securities, receivables, inventories, and fixed assets. Therefore, we can break the A^*/S_0 ratio into its components—cash/sales, inventories/sales, and so forth. Then,

$$\frac{A^*}{S_0} = \frac{A^* - \text{Inventories}}{S_0} + \frac{\text{Inventories}}{S_0} = 1.6$$

We know that the inventory turnover ratio is: Sales/inventories = 3. Therefore, inventories/sales = 1/3 = 0.3333. Further, if the inventory turnover ratio can be increased to 4, then the inventory/sales ratio will fall to 1/4 = 0.25, a difference of 0.3333 − 0.2500 = 0.0833. This, in turn, causes the A^*/S_0 ratio to fall from $A^*/S_0 = 1.6$ to $A^*/S_0 = 1.6 - 0.0833 = 1.5167$. This change has two effects: First, it changes the AFN equation; and second, it means that Barnsdale currently has excessive inventories. Because it is costly to hold excess inventories, Barnsdale will want to reduce its inventory holdings by not replacing inventories until the excess amounts have been used. We can account for this by setting up the revised AFN equation (using the new A^*/S_0 ratio), estimating the funds that will be needed next year if no excess inventories are currently on hand, and then subtracting out the excess inventories that are currently on hand:

Present Conditions:

$$\frac{\text{Sales}}{\text{Inventories}} = \frac{\$100}{\text{Inventories}} = 3$$

so

$$\text{Inventories} = \$100/3 = \$33.3 \text{ million at present}$$

New Conditions:

$$\frac{\text{Sales}}{\text{Inventories}} = \frac{\$100}{\text{Inventories}} = 4$$

so

$$\text{New level of inventories} = \$100/4 = \$25 \text{ million}$$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Therefore,

$$\text{Excess inventories} = \$33.3 - \$25 = \$8.3 \text{ million}$$

Forecast of Funds Needed, First Year:

$$\Delta S \text{ in first year} = 0.2(\$100 \text{ million}) = \$20 \text{ million}$$

$$\begin{aligned} \text{AFN} &= 1.5167(\$20) - 0.4(\$20) - 0.1(0.55)(\$120) - \$8.3 \\ &= \$30.3 - \$8 - \$6.6 - \$8.3 \\ &= \$7.4 \text{ million} \end{aligned}$$

Forecast of Funds Needed, Second Year:

$$\Delta S \text{ in second year} = gS_1 = 0.2(\$120 \text{ million}) = \$24 \text{ million}$$

$$\begin{aligned} \text{AFN} &= 1.5167(\$24) - 0.4(\$24) - 0.1(0.55)(\$144) \\ &= \$36.4 - \$9.6 - \$7.9 \\ &= \$18.9 \text{ million} \end{aligned}$$

ST-3 a. $$\text{Full capacity sales} = \frac{\text{Current sales}}{\text{Percentage of capacity at which FA were operated}} = \frac{\$36{,}000}{0.75} = \$48{,}000$$

$$\begin{aligned} \text{Percentage increase} &= \frac{\text{New sales} - \text{Old sales}}{\text{Old sales}} = \frac{\$48{,}000 - \$36{,}000}{\$36{,}000} = 0.33 \\ &= 33\% \end{aligned}$$

Therefore, sales could expand by 33% before Van Auken Lumber would need to add fixed assets.

b. **Van Auken Lumber: Projected Income Statement for December 31, 2017 (Thousands of Dollars)**

	2016	Forecast Basis	2017
Sales	$ 36,000	$1.25(\text{Sales}_{13})$	$ 45,000
Operating costs	30,783	$85.508\%(\text{Sales}_{14})$	38,479
EBIT	$ 5,217		$ 6,521
Interest	717	$12\%(\text{Debt}_{13})$	1,017
EBT	$ 4,500		$ 5,504
Taxes (40%)	1,800		2,202
Net income	$ 2,700		$ 3,302
Dividends (60%)	$ 1,620		$ 1,981
Additions to RE	$ 1,080		$ 1,321

Van Auken Lumber: Projected Balance Sheet for December 31, 2017 (Thousands of Dollars)

	2013	Percent of 2014 Sales	Additions	2014	LOC	2014 after AFN
Cash	$ 1,800	5%		$ 2,250		$ 2,250
Receivables	10,800	30		13,500		13,500
Inventories	12,600	35		15,750		15,750
Total current assets	$25,200			$31,500		$31,500
Net fixed assets	21,600			21,600[a]		21,600
Total assets	$46,800			$53,100		$53,100
Accounts payable	$ 7,200	20		$ 9,000		$ 9,000
Notes payable	3,472			3,472		3,472
Line of credit	0			0	2,549	2,549
Accruals	2,520	7		3,150		3,150
Total current liabilities	$13,192			$15,622		$18,171
Mortgage bonds	5,000			5,000		5,000
Common stock	2,000			2,000		2,000
Retained earnings	26,608		1,321[b]	27,929		27,929
Total liabilities and equity	$46,800			$50,551		$53,100
Financing deficit =				$ 2,549		

[a] From Part a we know that sales can increase by 33% before additions to fixed assets are needed.

[b] See income statement.

CHAPTER 14

ST-1 a.

Capital investments	$6,000,000
Projected net income	$5,000,000
Required equity = 60%(Capital inv.)	$3,600,000
Available residual	$1,400,000
Shares outstanding	1,000,000

DPS = $1,400/1,000,000 shares = $1.40

b. EPS = $5,000,000/1,000,000 shares = $5.00
Payout ratio = DPS/EPS = $1.4/$5 = 28%, or
Total dividends ÷ NI = $1,400,000/$5,000,000 = 28%

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

ST-2 a.

Value of operations	$2,100
+ Value of ST investments	$ 100
Total intrinsic value of firm	$2,200
− Debt	$ 200
− Preferred stock	$ 0
Intrinsic value of equity	$2,000
÷ Number of shares	100
Intrinsic price per share	$ 20

b.

Value of operations	$2,100
+ Value of ST investments	$ 0
Total intrinsic value of firm	$2,100
− Debt	$ 200
− Preferred stock	$ 0
Intrinsic value of equity	$1,900
÷ Number of shares	100
Intrinsic price per share	$ 19

c. The price before the repurchase, during the repurchase, and after the repurchase doesn't change. So the number of shares after the repurchase is the value of equity after the repurchase divided by the original price: $n_{Post} = \$1{,}900/\$20 = 95$.

Value of operations	$2,100
+ Value of ST investments	$ 0
Total intrinsic value of firm	$2,100
− Debt	$ 200
− Preferred stock	$ 0
Intrinsic value of equity	$1,900
÷ Number of shares	95
Intrinsic price per share	$ 20

CHAPTER 15

ST-1 a. $S = P(n) = \$30(600{,}000) = \$18{,}000{,}000$
$V = D + S = \$2{,}000{,}000 + \$18{,}000{,}000 = \$20{,}000{,}000$

b. $w_d = D/V = \$2{,}000{,}000/\$20{,}000{,}000 = 0.10$
$w_s = S/V = \$18{,}000{,}000/\$20{,}000{,}000 = 0.90$
$WACC = w_d r_d(1 - T) + w_s r_s$
$= (0.10)(10\%)(0.60) + (0.90)(15\%) = 14.1\%$

c. $WACC = (0.50)(12\%)(0.60) + (0.50)(18.5\%) = 12.85\%$

Since $g = 0$, it follows that FCF = NOPAT.

$V_{opNew} = FCF/WACC = EBIT(1 - T)/0.1285 = \$4{,}700{,}000(0.60)/0.1285$
$= \$21{,}945{,}525.292$
$D = w_d(v_{op}) = 0.50(\$21{,}945{,}525.292) = \$10{,}972{,}762.646$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Since it started with $2 million debt, it will issue:

$D_{New} - D_{Old} = \$8{,}972{,}762.646 = \$10{,}972{,}762.646 - \$2{,}000{,}000.$

$S_{Post} = V_{opNew} - D_{New} = \$21{,}945{,}525.292 - \$10{,}972{,}762.646 = \$10{,}972{,}762.646$

(Alternatively, $S_{Post} = w_s(V_{opNew}) = 0.50(\$21{,}945{,}525.292) = \$10{,}972{,}762.646.$)

$$\begin{aligned} n_{Post} &= n_{Prior}\left[\frac{V_{opNew} - D_{New}}{V_{opNew} - D_{Old}}\right] \\ &= 600{,}000\left[\frac{\$21{,}945{,}525.292 - \$10{,}972{,}762.646}{\$21{,}945{,}525.292 - \$2{,}000{,}000}\right] \\ &= 600{,}000\left[\frac{\$10{,}972{,}762.646}{\$19{,}945{,}525.292}\right] \\ &= 330{,}082 \\ P_{Post} &= (V_{opNew} - D_{Old})/n_{Prior} \\ &= (\$21{,}945{,}525.292 - \$2{,}000{,}000)/600{,}000 \\ &= \$33.2425 \end{aligned}$$

Alternatively, after issuing debt and before repurchasing stock, the firm's equity, S_{Prior}, is worth $V_{opNew} + (D_{New} - D_{Old}) - D_{New} = \$21{,}945{,}525.292 + \$8{,}972{,}762.646 - \$10{,}972{,}762.646 = \$19{,}945{,}525.29$. The stock price prior to the repurchase is $P_{Prior} = S_{Prior}/n_{Prior} = \$19{,}945{,}525.29/600{,}000 = \$33.242542$. The firm used the proceeds of the new debt, $8,972,762.646, to repurchase X shares of stock at a price of $33.242542 per share. The number of shares it will repurchase is $X = \$8{,}972{,}762.646/\$33.242542 = 269{,}918.07$. Thus, there are $600{,}000 - 269{,}918.07 = 330{,}082$ shares remaining. As a check, the stock price should equal the market value of equity (S) divided by the number of shares: $P_0 = \$10{,}972{,}762.646/330{,}082 = \$33.2425$.

ST-2 a. LIC's current cost of equity is:

$$r_s = 6\% + 1.5(4\%) = 12\%$$

b. LIC's unlevered beta is:

$$b_U = 1.5/[1 + (1 - 0.40)(25\%/75\%)] = 1.5/1.2 = 1.25$$

c. LIC's levered beta at $D/S = 60\%/40\% = 1.5$ is:

$$b = 1.25[1 + (1 - 0.40)(60/40)] = 2.375$$

LIC's new cost of capital will be:

$$r_s = 6\% + (2.375)(4\%) = 15.5\%$$

CHAPTER 16

ST-1 The Calgary Company: Alternative Balance Sheets

	Restricted (40%)	Moderate (50%)	Relaxed (60%)
Current assets (% of sales)	$1,200,000	$1,500,000	$1,800,000
Fixed assets	600,000	600,000	600,000
Total assets	$1,800,000	$2,100,000	$2,400,000
Debt	$ 900,000	$1,050,000	$1,200,000
Equity	900,000	1,050,000	1,200,000
Total liabilities and equity	$1,800,000	$2,100,000	$2,400,000

The Calgary Company: Alternative Income Statements

	Restricted	Moderate	Relaxed
Sales	$3,000,000	$3,000,000	$3,000,000
EBIT	450,000	450,000	450,000
Interest (10%)	90,000	105,000	120,000
Earnings before taxes	$ 360,000	$ 345,000	$ 330,000
Taxes (40%)	144,000	138,000	132,000
Net income	$ 216,000	$ 207,000	$ 198,000
ROE	24.0%	19.7%	16.5%

ST-2 a. and b.

Income Statements for Year Ended December 31, 2016 (Thousands of Dollars)

	Vanderheiden Press		Herrenhouse Publishing	
	a	b	a	b
EBIT	$ 30,000	$ 30,000	$ 30,000	$ 30,000
Interest	12,400	14,400	10,600	18,600
Taxable income	$ 17,600	$ 15,600	$ 19,400	$ 11,400
Taxes (40%)	7,040	6,240	7,760	4,560
Net income	$ 10,560	$ 9,360	$ 11,640	$ 6,840
Equity	$100,000	$100,000	$100,000	$100,000
Return on equity	10.56%	9.36%	11.64%	6.84%

The Vanderheiden Press has a higher ROE when short-term interest rates are high, whereas Herrenhouse Publishing does better when rates are lower.

c. Herrenhouse's position is riskier. First, its profits and return on equity are much more volatile than Vanderheiden's. Second, Herrenhouse must renew its large short-term loan every year, and if the renewal comes up at a time when money is tight or when its business is depressed or both, then Herrenhouse could be denied credit, which could put it out of business.

CHAPTER 17

ST-1

$$\frac{\text{Euros}}{\text{C\$}} = \frac{\text{Euros}}{\text{US\$}} \times \frac{\text{US\$}}{\text{C\$}}$$

$$= \frac{0.98}{\$1} \times \frac{\$1}{1.5} = \frac{0.98}{1.5} = 0.6533 \text{ euros per Canadian dollar}$$

CHAPTER 18

ST-1 a. Using Equation 18-1 and solving for the number of new shares:

$$n_{New} = \frac{(\%\text{ owned by new investors})n_{Existing}}{1 - (\text{owned by new investors})}$$

$$= [0.20(20 \text{ million})]/(1 - 0.20) = 5 \text{ million}$$

b. Intrinsic stock price per share before the IPO $= V_{Pre-IPO}/n_{Existing}$

$= (\$500)/20 = \$25.00$

c. Using Equation 18-3:

$$P_{Offer} = \left[\frac{V_{Pre-IPO}}{F(n_{New}) + n_{Existing}}\right] = \$500/[(0.07)(5) + 20] = \$24.57$$

ST-2 a. Net proceeds per share $= (1 - 0.07)(\$20) = \$18.60$

Required proceeds after direct costs: $\$30 \text{ million} + \$800,000 = \$30.8 \text{ million}$

Number of shares $= \$30.8 \text{ million}/\$18.60 \text{ per share} = 1.656 \text{ million shares}$

b. Amount left on table $=$ (Closing price $-$ offer price)(Number of shares)

$= (\$22 - \$20)(1.656 \text{ million}) = \$3.312 \text{ million}$

c. Underwriting cost $= 0.07(\$20)(1.656) = \$2.318 \text{ million}$

Total costs $= \$0.800 + \$2.318 + \$3.312 = \$6.430 \text{ million}$

CHAPTER 19

ST-1 a. **Cost of Leasing:**

	Year 0	Year 1	Year 2	Year 3	Year 4
Lease payment	−$10,000	−$10,000	−$10,000	−$10,000	$0
Payment tax savings	4,000	4,000	4,000	4,000	0
Net cash flow	−$ 6,000	− $ 6,000	−$ 6,000	−$ 6,000	$0

PV of leasing @ 6% = −22,038

b. **Cost of Owning:**

In our solution, we will consider the $40,000 cost as a Year-0 outflow rather than including all the financing cash flows. The net effect is the same because the PV of the financing flows, when discounted at the after-tax cost of debt, is the cost of the asset.

	Year 0	Year 1	Year 2	Year 3	Year 4
Net purchase price	−$40,000				
Maintenance cost		−$1,000	−$1,000	−$1,000	−$1,000
Maintenance tax savings		400	400	400	400
Depreciation tax savings		5,280	7,200	2,400	1,120
Residual value					10,000
Residual value tax					−4,000
Net cash flow	−$40,000	$4,680	$6,600	$1,800	$6,520
PV of owning @ 6% = −23,035					

Since the present value of leasing is better than the present value of owning, the truck should be leased. Specifically, the NAL is $-\$22{,}038 - (-\$23{,}035) = \$997$.

c. Use the cost of debt because most cash flows are fixed by contract and thus are relatively certain; therefore, lease cash flows have about the same risk as the firm's debt. Also, leasing is considered as a substitute for debt. Use an after-tax cost rate to account for interest tax deductibility.

CHAPTER 20

ST-1 First issue: 10-year straight bonds with a 6% coupon.

Second issue: 10-year bonds with 4.5% annual coupon with warrants. Both bonds issued at par $1,000. Value of warrants = ?

First issue: N = 10, PV = −1000, PMT = 60, and FV = 1000; then solve for I/YR = r_d = 6%. (Since it sold for par, we should know that r_d = 6%.)

Second issue: $1,000 = Bond + Warrants. This bond should be evaluated at 6% (since we know the first issue sold at par) in order to determine its present value: N = 10, I/YR = r_d = 6, PMT = 45, and FV = 1000; then solve for PV = $889.60.

The value of the warrants can be determined as the difference between $1,000 and the second bond's present value:

$$\text{Value of warrants} = \$1{,}000 - \$889.6 = \$110.40$$

CHAPTER 21

ST-1 a. $HV_{U,2} = [FCF_2(1 + g_L)]/(r_{sU} - g_L) = [\$120(1.04)]/(0.08 - 0.4) = \$3,120$

b. $V_U = FCF_1/(1 + r_{sU}) + (FCF_2 + HV_{U,2})/(1 + r_{sU})^2$
$= (100/1.08) + (\$120 + \$3{,}120)/(1.08)^2 = \$2{,}870.37$

c. $TS_1 = r_d DT = 0.05(\$500)(0.4) = \$10$
$TS_2 = TS_1 = \$10$

d. $HV_{TS,2} = [TS_2(1 + g_L)]/(r_{sU} - g_L) = [\$10(1.04)]/0.08 - 0.4 = \$260$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

e. $V_{Tax\ shield} = TS_1/(1 + r_{sU}) + (TS_2 + HV_{TS,2})/(1 + r_{sU})^2$
$= (10/1.08) + (\$10 + \$260)/(1.08)^2 = \$240.74$

f. $V_{op} = V_U + V_{Tax\ shield} = \$2,870.37 + \$240.74 = \$3,111.11$

CHAPTER 22

ST-1 a. The unlevered cost of equity based on the pre-merger required rate of return and pre-merger capital structure is:

$$\begin{aligned} r_{sU} &= {}_{wd}r_d + w_s r_{sL} \\ &= 0.25(6\%) + 0.75(10\%) \\ &= 9\% \end{aligned}$$

The post-horizon levered cost of equity is:

$$\begin{aligned} r_{sL} &= r_{sU} + (r_{sU} - r_d)(D/S) \\ &= 9\% + (9\% - 7\%)(0.35/0.65) \\ &= 10.077\% \end{aligned}$$

$$\begin{aligned} WACC &= w_d r_d(1 - T) + w_s r_s \\ &= 0.35(7\%)(1 - 0.40) + 0.65(10.077\%) \\ &= 8.02\% \end{aligned}$$

b. The horizon value of unlevered operations is:

$$\begin{aligned} HV_{U,3} &= FCF_3(1 + g)/(r_{sU} - g) \\ &= [\$25(1.05)]/(0.09 - 0.05) \\ &= \$656.250 \text{ million} \end{aligned}$$

$$\begin{aligned} \text{Unlevered } V_{ops} &= \frac{\$10}{(1.09)^1} + \frac{\$20}{(1.09)^2} + \frac{\$25 + \$656.25}{(1.09)^3} \\ &= \$552.058 \text{ million} \end{aligned}$$

Tax shields in Years 1 through 3 are:

$$\begin{aligned} \text{Tax shield} &= \text{Interest} \times T \\ TS_1 &= \$28.00(0.40) = \$11.200 \text{ million} \\ TS_2 &= \$24.00(0.40) = \$9.600 \text{ million} \\ TS_3 &= \$20.28(0.40) = \$8.112 \text{ million} \end{aligned}$$

$$\begin{aligned} HV_{TS,3} &= TS_3(1 + g)/(r_{sU} - g) \\ &= [\$8.112(1.05)]/(0.09 - 0.05) \\ &= \$212.940 \text{ million} \end{aligned}$$

$$\begin{aligned} \text{Value of tax shield} &= \frac{\$11.2}{(1.09)^1} + \frac{\$9.6}{(1.09)^2} + \frac{\$8.112 + \$212.940}{(1.09)^3} \\ &= \$189.048 \text{ million} \end{aligned}$$

$$\begin{aligned} \text{Total value} &= \text{Unlevered } V_{ops} + \text{Value of tax shield} \\ &= \$552.058 + \$189.048 \\ &= \$741.106 \end{aligned}$$

CHAPTER 23

ST-1 a. The hypothetical bond in the futures contract has an annual coupon of 6% (paid semiannually) and a maturity of 20 years. At a price of 97'13 (this is the percent of par), a $1,000 par bond would have a price of $\$1,000(97 + 13/32)/100 = \$974.0625$. To find the yield: N = 40, PMT = 30, FV = 1000, PV = −974.0625; then I = 3.1143% per 6 months. The nominal annual yield is 2(3.1143%) = 6.2286%.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

b. In this situation, the firm would be hurt if interest rates were to rise by September, so it would use a short hedge or sell futures contracts. Because futures contracts are for $100,000 in Treasury bonds, the value of a futures contract is $97,406.25 and the firm must sell $5,000,000/$97,406.25 = 51.33 ≈ 51 contracts to cover the planned $5,000,000 September bond issue. Because futures maturing in June are selling for 97 13/32 of par, the value of Wansley's futures is about $51(\$97,406.25) = \$4,967,718.75$. Should interest rates rise by September, Wansley will be able to repurchase the futures contracts at a lower cost, which will help offset their loss from financing at the higher interest rate. Thus, the firm has hedged against rising interest rates.

c. The firm would now pay 13% on the bonds. With a 12% coupon rate, the PV of the new issue is only $4,646,361.83 (N = 40, I = 13/2 = 6.5, PMT = −0.12/2(5000000) = −300000, FV = −5000000; then solve for PV). Therefore, the new bond issue would bring in only $4,646,361.83, so the cost of the bond issue that is due to rising rates is $\$5,000,000 - \$4,646,361.83 = \$353,638.17$.

However, the value of the short futures position began at $4,967,718.75. Now, if interest rates increased by 1 percentage point, then the yield on the futures would go up to 7.2286%(7.2286 = 6.2286 + 1). To find the value of the futures contract, enter N = 40, I = 7.2286/2 = 3.6143 (from Part a), PMT = 3000, and FV = 100000; then solve for PV = $87,111.04 per contract. With 51 contracts, the value of the futures position is $4,442,663.04. (*Note:* If you don't round off in any previous calculations, then the PV comes to $4,442,668.38.)

Because Wansley Company sold the futures contracts for $4,967,718.75 and will, in effect, buy them back at $4,442,668.04, the firm would make a profit of $\$4,967,718 - \$4,445,668.04 = \$525,050.71$ profit on the transaction (if we ignore transaction costs).

Thus, the firm gained $525,050.71 on its futures position, but lost $353,638.17 on its underlying bond issue. On net, it gained $525,050.71 − $353,638.71 = $171,412.54.

CHAPTER 24

ST-1 a. Distribution to priority claimants (millions of dollars):

Total proceeds from the sale of assets	$1,150
Less:	
1. First mortgage (paid from sale of fixed assets)	700
2. Second mortgage (paid from sale of fixed assets after satisfying first mortgage: $750 − $700 = $50)	50
3. Fees and expenses of bankruptcy	1
4. Wages due to workers	60
5. Taxes due	90
Funds available for distribution to general creditors	$ 249

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

b. Distribution to general creditors (millions of dollars):

General Creditor Claims	Amount of Claim	Pro Rata Distribution[a]	Distribution after Subordinate Adjustment[b]	% of Original Claim Received
Unsatisfied second mortgage	$ 350	$ 60	$ 60	28%[c]
Accounts payable	100	17	17	17
Notes payable	300	52	86	29
Debentures	500	86	86	17
Subordinated debentures	200	34	0	0
Total	$1,450	$249	$249	

[a]Pro rata distribution: $\$249/\$1,450 = 0.172 = 17.2\%$.
[b]Subordinated debentures are subordinated to notes payable. Unsatisfied portion of notes payable is greater than subordinated debenture distribution, so subordinated debentures receive $0.
[b]Includes $50 from sale of fixed assets received in priority distribution.

Total distribution to second mortgage holders: $\$50 + \$60 = \$110$ million.

Total distribution to holders of notes payable: $86 million.

Total distribution to holders of subordinated debentures: $0 million.

Total distribution to common stockholders: $0 million.

CHAPTER 25

ST-1 a. For Security A:

P_A	r_A	$P_A r_A$	$(r_A - \hat{r}_A)$	$(r_A - \hat{r}_A)^2$	$P_A(r_A - \hat{r}_A)^2$
0.1	−10%	−1.0%	−25%	625	62.5
0.2	5	1.0	−10	100	20.0
0.4	15	6.0	0	0	0.0
0.2	25	5.0	10	100	20.0
0.1	40	4.0	25	625	62.5

$\hat{r}_A = 15.0\%$ $\sigma_A = \sqrt{165.0} = 12.8\%$

b.
$$w_A = \frac{\sigma_B(\sigma_B - \rho_{AB}\sigma_A)}{\sigma_A^2 + \sigma_B^2 - 2\rho_{AB}\sigma_A\sigma_B}$$
$$= \frac{25.7[25.7 - (-0.5)(12.8)]}{(12.8)^2 + (25.7)^2 - 2(-0.5)(12.8)(25.7)}$$
$$= \frac{824.97}{1,153.29} = 0.7153$$

There is 71.53% invested in A and 28.47% invested in B.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

c. $\sigma_p = \sqrt{(w_A\sigma_A)^2 + (1 - w_A)^2(\sigma_B)^2 + 2w_A(1 - w_A)\rho_{AB}\sigma_A\sigma_B}$

$= \sqrt{(0.75)^2(12.8)^2 + (0.25)^2(25.7)^2 + 2(0.75)(0.25)(-0.5)(12.8)(25.7)}$

$= \sqrt{92.16 + 41.28 - 61.68}$

$= \sqrt{71.76} = 8.47\%$ when $w_A = 75\%$

$\sigma_p = \sqrt{(0.7153)^2(12.8)^2 + (0.2847)^2(25.7)^2 + 2(0.7153)(0.2847)(-0.5)(12.8)(25.7)}$

$= 8.38\%$ when $w_A = 71.53\%$ (this is the minimum σ_P)

$\sigma_p = \sqrt{(0.5)^2(12.8)^2 + (0.5)^2(25.7)^2 + 2(0.5)(0.5)(-0.5)(12.8)(25.7)}$

$= 11.3\%$ when $w_A = 50\%$

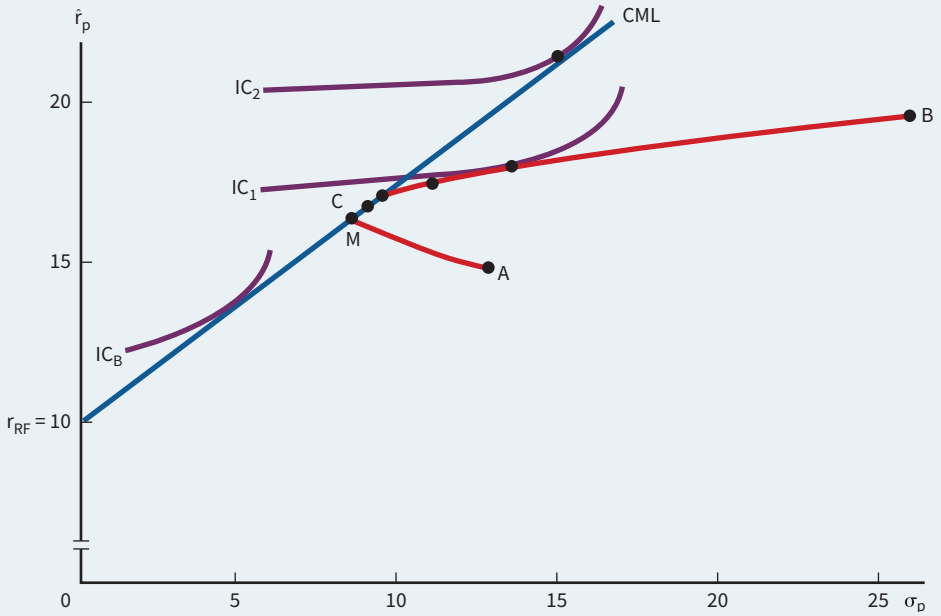
$\sigma_p = \sqrt{(0.25)^2(12.8)^2 + (0.75)^2(25.7)^2 + 2(0.25)(0.75)(-0.5)(12.8)(25.7)}$

$= 17.89\%$ when $w_A = 25\%$

% in A	% in B	r_p	σ_P
100.00%	0.00%	15.00%	12.8%
75.00	25.00	16.25	8.5
71.53	28.47	16.42	8.4
50.00	50.00	17.50	11.1
25.00	75.00	18.75	17.9

Calculations for preceding table:

$r_p = w_A(\hat{r}_A) + (1 - w_A)(\hat{r}_B)$



$= 0.75(15) + (0.25)(20) = 16.25\%$ when $w_A = 75\%$

$= 0.7153(15) + 0.2847(20) = 16.42\%$ when $w_{A0} = 71.53\%$

$= 0.5(15) + 0.5(20) = 17.50\%$ when $w_A = 50\%$

$= 0.25(15) + 0.75(20) = 18.75\%$ when $w_A = 25\%$

d. See graph below.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

e. See indifference curve IC_1 in the preceding graph. At the point where $\hat{r}_p = 18\%$, $\sigma_p = 13.5\%$.

$$\begin{aligned} \hat{r}_p &= w_A(\hat{r}_A) + (1 - w_A)(\hat{r}_B) \\ 18 &= w_A(15) + (1 - w_A)(20) \\ &= 15w_A + 20 - 20w_A \\ 5w_A &= 2 \\ w_A &= 0.4 \text{ or } 40\% \end{aligned}$$

Therefore, to an approximation, your optimal portfolio would have 40% in A and 60% in B, with $\hat{r}_p = 18\%$ and $\sigma_p = 13.5\%$. (We could get an exact σ_P by using $w_A = 0.4$ in the equation for σ_P.)

f. The existence of the riskless asset would enable you to go to the CAPM. We would draw in the CML as shown on the graph in Part d. Now you would hold a portfolio of stocks, borrowing on margin to hold more stocks than your net worth, and move to a higher indifference curve, IC_2.

You can put all of your money into the riskless asset, all in A, all in B, or some in each security. The most logical choices are (1) hold a portfolio of A and B plus some of the riskless asset, (2) hold only a portfolio of A and B, or (3) hold a portfolio of A and B and borrow to leverage the portfolio, assuming you can borrow at the riskless rate.

Reading from the graph, we see that your $\hat{r}_p$ at the point of tangency between your IC_2 and the CML is about 22%. We can use this information to find out how much you invest in the market portfolio and how much you invest in the riskless asset. (It will turn out that you have a *negative* investment in the riskless asset, which means that you borrow rather than lend at the risk-free rate.)

$$\begin{aligned} \hat{r}_p &= w_{RF}(r_{RF}) + (1 - w_{RF})(\hat{r}_M) \\ 22 &= w_{RF}(10) + (1 - w_{RF})(16.8) \\ &= 10w_{RF} + 16.8 - 16.8w_{RF} \\ -6.8w_{RF} &= 5.2 \\ w_{RF} &= -0.76 \text{ or } -76\% \text{ (which means that you borrow)} \\ 1 - w_{RF} &= 1.0 - (-0.76) \\ &= +1.76 \text{ or } 176\% \text{ in the market portfolio} \end{aligned}$$

Hence, this investor, with \$200,000 of net worth, buys stock with a value of $\$200,000(1.76) = \$352,000$ and borrows \$152,000.

The risk of this leveraged portfolio is:

$$\begin{aligned} \sigma_p &= \sqrt{(-0.76)^2(0)^2 + (1.76)^2(8.5)^2 + 2(-0.76)(1.76)(0)(8.5)(0)} \\ &= \sqrt{(1.76)^2(8.5)^2} \\ &= (1.76)(8.5) = 15\% \end{aligned}$$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Your indifference curve suggests that you are not very risk averse. A risk-averse investor would have a steep indifference curve (visualize a set of steep curves that were tangent to CML to the left of Point C). This investor would hold some of A and B, combined to form portfolio M, and some of the riskless asset.

g. Given your assumed indifference curve, you would, when the riskless asset becomes available, change your portfolio from the one found in Part e (with $\hat{r}_p = 18\%$ and $\sigma_p = 13.5\%$) to one with $\hat{r}_p \approx 22.0\%$ and $\sigma_p \approx 15.00\%$.

h.
$$\begin{aligned} r_A &= r_{RF} + (r_M - r_{RF})b_A \\ 15 &= 10 + (16.8 - 10)b_A \\ &= 10 + (6.8)b_A \\ b_A &= 0.74 \\ 20 &= 10 + (6.8)b_B \\ b_B &= 1.47 \end{aligned}$$

Note that the 16.8% value for r_M was approximated from the graph. Also, this solution *assumes* that you can borrow at $r_{RF} = 10\%$. This is a basic—but questionable—CAPM assumption. If the borrowing rate is *above* r_{RF}, then the CML would turn down to the right of Point M.

CHAPTER 26

ST-1 a. NPV of each demand scenario:

0	Probability	Future Cash Flows Year 1	Future Cash Flows Year 2	NPV This Scenario	Probability × NPV
	25%	$13	$13	$13.13	$3.28
−$8	50%	$7	$7	$3.38	$1.69
	25%	$1	$1	−$6.37	−$1.59
			Expected NPV of future CFs =		$3.38

NPV under high-demand scenario:

$$NPV = -\$8 + \frac{\$13}{(1+0.15)^1} + \frac{\$13}{(1+0.15)^2} = \$13.13$$

NPV under medium-demand scenario:

$$NPV = -\$8 + \frac{\$7}{(1+0.15)^1} + \frac{\$7}{(1+0.15)^2} = \$3.38$$

NPV under low-demand scenario:

$$NPV = -\$8 + \frac{\$1}{(1+0.15)^1} + \frac{\$1}{(1+0.15)^2} = -\$6.37$$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Expected NPV = 0.25($13.13) + 0.50($3.38) + 0.25(−$6.37) = $3.38 million.

b. NPV of operating cash flows if the additional project is implemented only when optimal:

	Future Operating Cash Flows (Discount at WACC)					
Probability	Year 1	Year 2	Year 3	Year 4	NPV This Scenario	Probability × NPV
25% ↗	$13	$13	$13	$13	$37.11	$9.28
50% →	$7	$7	$7	$7	$19.98	$9.99
25% ↘	$1	$1	$0	$0	$1.63	$0.41
					Expected NPV of future operating CFs =	$19.68

NPV of operating cash flows under high-demand scenario:

$$\text{NPV} = \frac{\$13}{(1+0.15)^1} + \frac{\$13}{(1+0.15)^2} + \frac{\$13}{(1+0.15)^3} + \frac{\$13}{(1+0.15)^4} = \$37.11$$

NPV of operating cash flows under medium-demand scenario:

$$\text{NPV} = \frac{\$7}{(1+0.15)^1} + \frac{\$7}{(1+0.15)^2} + \frac{\$7}{(1+0.15)^3} + \frac{\$7}{(1+0.15)^4} = \$19.98$$

NPV of operating cash flows under low-demand scenario:

$$\text{NPV} = \frac{\$1}{(1+0.15)^1} + \frac{\$1}{(1+0.15)^2} = \$1.63$$

$$\begin{aligned}\text{Expected NPV of operating cash flows} &= 0.25(\$37.11) + 0.50(\$19.98) \\ &\quad +0.25(\$1.63) \\ &= \$19.68 \text{ million}\end{aligned}$$

Find NPV of costs, discounted at risk-free rate:

0	Probability	Year 1	Year 2	NPV This Scenario	Probability × NPV
	25% ↗	$0	−$8	−$15.12	−$3.78
−$8	50% →	$0	−$8	−$15.12	−$7.56
	25% ↘	$0	$0	−$8.00	−$2.00
				Expected NPV of future operating CFs =	−$13.34

NPV of costs under high-demand scenario:

$$\text{NPV} = -\$8 + \frac{\$0}{(1+0.06)^1} + \frac{-\$8}{(1+0.06)^2} = -\$15.12$$

NPV of costs under medium-demand scenario:

$$\text{NPV} = -\$8 + \frac{\$0}{(1+0.06)^1} + \frac{-\$8}{(1+0.06)^2} = -\$15.12$$

NPV of costs under low-demand scenario:

$$\text{NPV} = -\$8 + \frac{\$0}{(1+0.06)^1} + \frac{\$0}{(1+0.06)^2} = -\$8.00$$

$$\begin{aligned}\text{Expected NPV of costs} &= 0.25(-\$15.12) + 0.50(-\$15.12) + 0.25(-\$8.00)\\ &= -\$13.34 \text{ million}\end{aligned}$$

$$\begin{aligned}\text{Expected NPV of project} &= \text{Expected NPV of operating cash flows} - \text{Expected NPV of costs}\\ &= \$19.68 - \$13.34 = \$6.34\end{aligned}$$

c. Find the expected NPV of the additional project's operating cash flows, which is analogous to the "stock price" in the Black-Scholes model:

0	Probability	Year 1	Year 2	Year 3	Year 4	NPV of This Scenario	Probability × NPV
	25% ↗	$0	$0	$13	$13	$15.98	$4.00
	50% →	$0	$0	$7	$7	$8.60	$4.30
	25% ↘	$0	$0	$1	$1	$1.23	$0.31
						Expected NPV future operating CFs =	$8.60

NPV of operating cash flows under high-demand scenario:

$$\text{NPV} = \frac{\$0}{(1+0.15)^1} + \frac{\$0}{(1+0.15)^2} + \frac{\$13}{(1+0.15)^3} + \frac{\$13}{(1+0.15)^4} = \$15.98$$

NPV of operating cash flows under medium-demand scenario:

$$\text{NPV} = \frac{\$0}{(1+0.15)^1} + \frac{\$0}{(1+0.15)^2} + \frac{\$7}{(1+0.15)^3} + \frac{\$7}{(1+0.15)^4} = \$8.60$$

NPV of operating cash flows under low-demand scenario:

$$\text{NPV} = \frac{\$0}{(1+0.15)^1} + \frac{\$0}{(1+0.15)^2} + \frac{\$1}{(1+0.15)^3} + \frac{\$1}{(1+0.15)^4} = \$1.23$$

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

$$\begin{aligned}\text{Expected NPV of additional project's operating cash flows} &= 0.25(\$15.98) + 0.50(\$8.60) \\ &\quad +0.25(\$1.23) \\ &= \$8.60 \text{ million}\end{aligned}$$

The inputs for the Black-Scholes model are: $r_{RF} = 0.06$, $X = 8$, $P = 8.6$, $t = 2$, and $\sigma^2 = 0.150$. Using these inputs, the value of the option, V, is:

$$d_1 = \frac{1n(P/X) + \left[r_{RF} + \frac{\sigma^2}{2}\right] \times t}{\sigma\sqrt{t}} = \frac{1n(8.6/8) + \left[0.06 + \frac{0.150}{2}\right] \times 2}{\sqrt{0.15}\sqrt{2}} = 0.62499$$

$$d_2 = d_1 - \sigma\sqrt{t} = 0.62499 - \sqrt{0.15}\sqrt{2} = 0.07727$$

Use *Excel*'s NORMSDIST function to calculate $N(d_1)$ and $N(d_2)$:

$$\begin{aligned}N(d_1) &= 0.73401 \\ N(d_2) &= 0.53079\end{aligned}$$

$$V = P[N(d_1)] - Xe^{-r_{RF}t}[N(d_2)] = 8.6(0.73401) - 8e^{-0.06(2)}(0.53079) = \$2.55 \text{ million}$$

The total value is the value of the original project (from Part a) and the value of the growth option:

$$\text{Total value} = \$3.38 + \$2.55 = \$5.93 \text{ million}$$

APPENDIX B

Answers to End-of-Chapter Problems

We present here some intermediate steps and final answers to selected end-of-chapter problems. Please note that your answer may differ slightly from ours because of rounding differences. Also, although we hope not, some of the problems may have more than one correct solution, depending on what assumptions are made when working the problem. Finally, many of the problems involve some verbal discussion as well as numerical calculations; this verbal material is not presented here.

2-1 5.8%.

2-2 25%.

2-3 $3,000,000.

2-4 $2,000,000.

2-5 $3,600,000.

2-6 $25,000,000.

2-7 Taxable income = $319,500;
Marginal tax rate = 39%;
Tax = $107,855;
NI = $222,145;
Average tax rate = 33.8%.

2-8 a. Tax = $3,575,000.
b. Tax = $350,000.
c. Tax = $105,000.

2-9 AT&T bond = 4.875%;
AT&T preferred stock =5.37%;
Florida bond = 5%.

2-10 NI = $450,000;
NCF = $650,000.

2-11 a. NI = $900,000;
Net CF = $2,400,000.
b. NI = $0;
Net CF = $3,000,000.
c. NI = $1,350,000;
Net CF = $2,100,000.

2-12 a. NOPAT = $756 million.
b. $NOWC_{15}$ = $3.0 billion;
$NOWC_{16}$ = $3.3 billion.
c. Op. $capital_{15}$ = $6.5 billion;
Op. $capital_{16}$ = $7.15 billion.
d. FCF = $106 million.
e. ROIC = 10.57%.
f. Answers in millions:
A-T int. = $72;
Inc. in debt = −$284;
Div. = $220;

Constant growth: $\hat{r}_s = \frac{D_1}{P_0} + g_L$

Expected dividend yield $= \frac{D_1}{P_0}$

Expected capital gains yield $= \frac{\hat{P}_1 - P_0}{P_0}$

$\hat{r}_s$ = Expected rate of return on stock = Expected dividend yield + Expected capital gains yield

$= \frac{D_1}{P_0} + \frac{\hat{P}_1 - P_0}{P_0}$

$\bar{r}_s$ = Actual dividend yield + Actual capital gains yield

For a zero growth stock, $\hat{P}_0 = \frac{D}{r_s}$

Horizon value of stock $= \hat{P}_T = \frac{D_{T+1}}{r_s - g_L} = \frac{D_T(1 + g_L)}{r_s - g_L}$

$V_{ps} = \frac{D_{ps}}{r_{ps}}$

$\hat{r}_{ps} = \frac{D_{ps}}{V_{ps}}$

CHAPTER 8

Exercise value = MAX[Current price of stock − Strike price, 0]

Number of stock shares in hedged portfolio $= N = \frac{C_u - C_d}{P_u - P_d}$

$V_C = P[N(d_1)] - Xe^{-r_{RF}t}[N(d_2)]$

$d_1 = \frac{\ln(P/X) + [r_{RF} + (\sigma^2/2)]t}{\sigma\sqrt{t}}$

$d_2 = d_1 - \sigma\sqrt{t}$

Put–call parity: Put option $= V_C - P + Xe^{-r_{RF}t}$

V of put $= P[N(d_1) - 1] - Xe^{-r_{RF}t}[N(d_2) - 1]$

CHAPTER 9

After-tax component cost of debt $= r_d(1 - T)$

$M(1 - F) = \sum_{t=1}^{N} \frac{INT(1 - T)}{[1 + r_d(1 - T)]^t} + \frac{M}{[1 + r_d(1 - T)]^N}$

$r_{ps} = \frac{D_{ps}}{P_{ps}(1 - F)}$

$$\text{Horizon value of unlevered firm} = HV_{U,N} = \frac{FCF_{N+1}}{r_{sU} - g_L} = \frac{FCF_N(1 + g_L)}{r_{sU} - g_L}$$

$$\text{Horizon value of tax shield} = HV_{TS,N} = \frac{TS_{N+1}}{r_{sU} - g_L} = \frac{TS_N(1 + g_L)}{r_{sU} - g_L}$$

$$V_{\text{Unlevered}} = \sum_{t=1}^{N} \frac{FCF_t}{(1 + r_{sU})^t} + \frac{HV_{U,N}}{(1 + r_{sU})^N}$$

$$V_{\text{Tax shield}} = \sum_{t=1}^{N} \frac{TS_t}{(1 + r_{sU})^t} + \frac{HV_{TS,N}}{(1 + r_{sU})^N}$$

$$\text{Value of operations} = V_{op} = V_{\text{Unlevered}} + V_{\text{Tax shield}}$$

Free Cash Flow to Equity:

$$\text{FCFE} = \text{Free cash flow} - \text{After-tax interest expense} - \text{Principal payments} + \text{Newly issued debt}$$

$$= \text{Free cash flow} - \text{Interest expense} + \text{Interest tax shield} + \text{Net change in debt}$$

$$\text{FCFE} = \text{Net income} - \text{Net investment in operating capital} + \text{Net change in debt}$$

$$HV_{FCFE,N} = \frac{FCFE_{N+1}}{r_{sL} - g_L} = \frac{FCFE_N(1 + g_L)}{r_{sL} - g_L}$$

$$V_{FCFE} = \sum_{t=1}^{N} \frac{FCFE_t}{(1 + r_{sL})^t} + \frac{HV_{FCFE,N}}{(1 + r_{sL})^N}$$

$$S = V_{FCFE} + \text{Nonoperating assets}$$

CHAPTER 22

$$\frac{\text{Total value of shares to target shareholders}}{\text{Total post-merger value of equity}} = \text{Percent required by target stockholders} = \frac{n_{New}}{n_{New} + n_{Old}}$$

CHAPTER 25

$$\hat{r}_p = w_A \hat{r}_A + (1 - w_A)\hat{r}_B$$

$$\text{Portfolio SD} = \sigma_p = \sqrt{w_A^2\sigma_A^2 + (1 - w_A)^2\sigma_B^2 + 2w_A(1 - w_A)\rho_{AB}\sigma_A\sigma_B}$$

$$\text{Minimum-risk portfolio: } w_A = \frac{\sigma_B(\sigma_B - \rho_{AB}\sigma_A)}{\sigma_A^2 + \sigma_B^2 - 2\rho_{AB}\sigma_A\sigma_B}$$

$$\hat{r}_p = \sum_{i=1}^{N}(w_i\hat{r}_i)$$

$$\sigma_p^2 = \sum_{i=1}^{N}\sum_{j=1}^{N}(w_i w_j \sigma_i \sigma_j \rho_{ij})$$

$$\sigma_p^2 = \sum_{i=1}^{N} w_i^2\sigma_i^2 + \sum_{i=1}^{N}\sum_{\substack{j=1 \\ j\neq i}}^{N} w_i\sigma_i w_j\sigma_j\rho_{ij}$$

$$\sigma_p = \sqrt{(1 - w_{RF})^2\sigma_M^2} = (1 - w_{RF})\sigma_M$$

$$\text{CML: } \hat{r}_p = r_{RF} + \left(\frac{\hat{r}_M - r_{RF}}{\sigma_M}\right)\sigma_p$$

$$r_i = r_{RF} + \frac{(r_M - r_{RF})}{\sigma_M}\left(\frac{\text{Cov}(r_i, r_M)}{\sigma_M}\right) = r_{RF} + (r_M - r_{RF})\left(\frac{\text{Cov}(r_i, r_M)}{\sigma_M^2}\right)$$

$$b_i = \frac{\text{Covariance between Stock i and the market}}{\text{Variance of market returns}} = \frac{\text{Cov}(r_i, r_M)}{\sigma_M^2} = \frac{\rho_{iM}\sigma_i\sigma_M}{\sigma_M^2} = \rho_{iM}\left(\frac{\sigma_i}{\sigma_M}\right)$$

$$\text{SML} = r_i = r_{RF} + (r_M - r_{RF})b_i = r_{RF} + (RP_M)b_i$$

$$\text{Sharpe reward-to-variability ratio} = \frac{r_{p,\,Avg} - r_{RF,\,Avg}}{\sigma\text{ of}(r_{p,Avg} - r_{RF,Avg})}$$

$$\text{Treynor reward-to-volatility ratio} = \frac{r_{p,\,Avg} - r_{RF,\,Avg}}{b_p}$$

$$\sigma_i^2 = b_i^2\sigma_M^2 + \sigma_{e_i}^2$$

$$\text{APT: } r_i = r_{RF} + (r_1 - r_{RF})b_{i1} + \cdots + (r_j - r_{RF})b_{ij}$$

CHAPTER 26

$$\text{CV} = \frac{\sigma(\text{PV of future CF})}{\text{E}(\text{PV of future CF})}$$

$$\text{Variance of project's rate of return: } \sigma^2 = \frac{\ln(\text{CV}^2 + 1)}{t}$$

Glossary

A

agency conflict Conflicts between owners, managers, employees, and creditors occurring when one of these groups acts on its own behalf at the expense of one or more of the other groups.

401(k) retirement plan Employees' contributions, matching contributions from the sponsoring employer (if these are included in the plan), and profits on the investments are not taxable until withdrawn.

501(c)(3) corporation A charitable organization that meets the IRS requirements for tax-exempt status under the tax code section 501(c)(3).

abandonment option Allows a company to reduce the capacity of its output in response to changing market conditions. This includes the option to contract production or abandon a project if market conditions deteriorate too much.

abnormal yield curve A downward-sloping yield curve. Also called an inverted yield curve.

absolute priority doctrine States that claims must be paid in strict accordance with the priority of each claim, regardless of the consequence to other claimants.

accelerated depreciation method Depreciation method that has larger depreciation rates in the early years when compared to straight-line depreciation and has smaller depreciation rates in the latter years.

account payable Represents the amount a company owes a supplier when purchasing a product or service with credit extended by the seller. It is a current liability from the purchaser's perspective and a current asset from the seller's. The balance of the account payable is reduced to zero when the company actually pays its supplier. Often just called payables.

account receivable Represents the amount a customer owes a company when the company extends credit to the purchaser of a product or service. It is a current asset from the selling company's perspective and a current liability from the purchaser's. The balance of the account receivable is reduced to zero when the company collects a cash payment from the purchaser. Often just called receivables.

accounting beta Estimated by using *accounting return on assets* instead of stock returns.

accounting beta method Method of estimating a divisional beta by running a regression of the division's *accounting return on assets* against the *average return on assets* for the market.

accounting income Income as defined by Generally Accepted Accounting Principles (GAAP). Also called net income, accounting profit, profit, or earnings.

accounting profit A firm's net income as reported on its income statement. It is also called earnings or profit.

accredited investors Officers and directors of a privately held company, high-wealth individuals, and institutional investors. Allowed to purchase securities in a nonregistered private placement, but cannot subsequently sell their securities in the secondary market to the general public.

accruals Amounts owed (i.e., accrued) for expense but that have not yet been paid. Common examples are wages and taxes, which are paid periodically rather than daily.

acid test ratio Indicates the extent to which current liabilities are covered by the most liquid current assets; it is found by subtracting inventories from current assets and then dividing this difference by current liabilities. It is also called the current ratio.

acquiring company A company that seeks to acquire another firm.

actual rate of return on stock, $\bar{r}_s$ The actual rate of return on a share of stock during a particular holding period. Also called the realized rate of return on stock.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

actuarial rate of return The discount rate used to determine the present value of future benefits under a defined benefits pension plan.

additional funds needed (AFN) Those funds required from external sources to increase the firm's assets to support a sales increase. A sales increase will normally require an increase in assets. However, some of this increase is usually offset by a spontaneous increase in liabilities as well as by earnings retained in the firm. Those funds that are required but not generated internally must be obtained from external sources.

add-on interest Interest is calculated over the life of the loan as the product of the initial amount borrowed, the number of years until full repayment, and the annual rate on the loan. This total interest charge is added to the loan amount to get the total amount of payments. The total amount of payments is divided by the number of payments periods to get an equal "installment" payment each period. This raises the effective cost of the loan.

adjustable rate preferred stock (ARP) Instead of fixed dividends has dividend payments that are linked to rates on Treasury securities.

adjusted beta Adjustment to historical beta that reflects knowledge of the distribution of true betas (i.e., average beta is equal to 1). If estimated beta is greater than 1, then adjusted beta is between 1 and the estimated beta; if the estimated beta is less than 1, the adjusted beta is between the estimated beta and 1.

adjusted present value approach (APV) Defines the value of a levered firm as the sum of an unlevered firm's value plus the value of side effects due to leverage. The side effects often include the present value of annual tax savings each year and the present value of any expected financial distress costs.

adjustment bureau Group sponsored by a local credit managers' association for the purpose of helping creditors and borrowers work out problems without having to go through formal bankruptcy proceedings.

after-tax cost of debt, $(1-T)r_d$ A company's after-tax cost of providing the required rate of return on debt.

agency cost or problem An expense, either direct or indirect, that is borne by a principal as a result of having delegated authority to an agent. An example is the costs borne by shareholders to encourage managers to maximize a firm's stock price rather than act in their own self-interests. These costs may also arise from lost efficiency and the expense of monitoring management to ensure that debtholders' rights are protected.

agency debt Debt issued by federal agencies such as the Tennessee Value Authority. Agency debt is not officially backed by the full faith and credit of the U.S. government, but investors assume that the government implicitly guarantees this debt, so these bonds carry interest rates only slightly higher than Treasury bonds.

agency relationship Arises whenever someone (the principal) hires someone (an agent) to perform a service and gives the agent decision-making authority to act on behalf of the principal.

agent A person or organization to whom a principal has delegated decision-making authority, usually with the intent for the agent to act on behalf of the principal.

aggressive approach (for short-term financing) Refers to a policy in which a firm finances all of its fixed assets with long-term capital but part of its permanent current assets with short-term bank loans.

aging schedule Breaks down accounts receivable according to how long they have been outstanding. This gives the firm a more complete picture of the structure of accounts receivable than that provided by days sales outstanding.

alternative minimum tax (AMT) A provision of the U.S. Tax Code that requires profitable firms to pay at least some taxes if such taxes are greater than the amount due under standard tax accounting.

alternative trading system (ATS) A type of trading venue that can be registered with the SEC but that does not have as stringent requirements as a registered stock exchange. Commonly called "dark pools" because they do not have to report any pre-trade quotes.

American option An option which may be exercised on or before the exercise date.

amortization expense A noncash charge on the income statement to reflect a decrease in value of an intangible asset, such as goodwill.

amortization schedule A table that breaks down the periodic fixed payment of an installment loan into its principal and interest components.

amortized loan A loan that is repaid in equal periodic amounts (or "killed off") over time.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

anchoring bias Occurs when predictions of future events are influenced too heavily by recent events.

angel investors Wealthy individual investors providing early external financing for a start-up company by purchasing equity. Often have helpful experience and industry contacts.

annual compounding When interest is compounded once per year.

annual percentage rate (APR) The rate required to be reported by the Truth in Lending Act. It is the nominal annual interest rate found by multiplying the periodic rate by the number of periods.

annual report A report issued annually by a corporation to its stockholders. It contains basic financial statements as well as management's opinion of the past year's operations and the firm's future prospects.

annual vesting A certain percentage of the options in a grant vest each year. For example, one-third of the options in the grant might vest each year.

annuity A series of payments of a fixed amount for a specified number of periods.

annuity due An annuity with payments occurring at the beginning of each period.

APR The rate required to be reported by the Truth in Lending Act. It is the nominal annual interest rate found by multiplying the periodic rate by the number of periods.

arbitrage The simultaneous buying and selling of the same commodity or security in two different markets at different prices, thus yielding a risk-free return. The person engaging in arbitrage has no personal funds invested, has no risk, and has a guaranteed payoff.

Arbitrage Pricing Theory (APT) An approach to measuring the equilibrium risk–return relationship for a given stock as a function of multiple factors, rather than the single factor (the market return) used by the CAPM. The APT is based on complex mathematical and statistical theory, and it can account for several factors (such as GNP and the level of inflation) in determining the required return for a particular stock.

arrearages Preferred dividends that have not been paid and hence are "in arrears."

ask quote (or ask price) Price at which investor is willing to sell a stock or other security.

asset allocation models Used by pension fund managers to make funding and investment decisions; these models use computer simulations to examine the risk/return characteristics of portfolios with various mixes of assets.

asset management ratios A set of ratios that measure how effectively a firm is managing its assets. Also called efficiency ratios.

asset-backed security A new security that represents a claim on a specific portfolio of financial assets, such as a portfolio of credit card debts or mortgages.

assignee (in informal liquidation) Third party in an informal liquidation, to whom title of debtor's assets is transferred for the purpose of liquidating the assets.

assignment (in informal liquidation) An informal procedure for liquidating debts that transfers title to a debtor's assets to a third person, known as an assignee or trustee, who then sells the assets.

asymmetric hedge Occurs for a derivative in which the payoff from a dollar increase in the underlying asset does not have exactly the opposite effect of a dollar decrease in the underlying asset. For example, consider a call option's payoffs when the current price of the underlying asset is equal to the option's strike price. A $1 increase in the asset's price causes a $1 increase in the option's payoff, whereas a $1 decline in the asset's price doesn't change the payoff.

asymmetric information theory (capital structure) Assumes managers have more complete information than investors and will issue stock when it is overvalued, causing a negative signal. Leads to a preferred "pecking order" of financing: (1) retained earnings, followed by (2) debt, and then (3) new common stock. Also known as the capital structure signaling theory.

attainable set Represents all portfolios that can be constructed from a given set of stocks; also known as the feasible set.

automated matching engine Part of a computer system in which buyers and sellers post orders and then let the computer automatically match and execute trades.

automated trading platform Computer system in which buyers and sellers post orders. Trades are automatically executed for matching orders.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

automatic stay (in bankruptcy) Bankruptcy provision forced on all lenders to prevent any from foreclosing to collect on their loans. Allows borrowing firm to remain a going concern.

average collection period (ACP) Used to appraise accounts receivable and indicates the length of time the firm must wait after making a sale before receiving cash. It is found by dividing receivables by average daily sales. Also called the days sales outstanding and receivables conversion period.

average return, $\bar{r}_{Avg}$ The average return from a sample periods of past actual returns.

average tax rate Calculated by taking the total amount of tax paid divided by taxable income.

B

bait and switch Strategy of raising funds through debt financing and investing the funds in riskier projects than anticipated by the lenders.

balance sheet A statement of the firm's financial position at a specific point in time. The firm's assets are listed on the left-hand side of the balance sheet; the right-hand side shows its liabilities and equity, or the claims against these assets.

banker's acceptance Created when an importer's bank promises to accept a postdated check written to an exporter even if there are insufficient funds in the importer's account. If the bank is strong, then this financial instrument virtually eliminates credit risk.

bankruptcy costs Direct costs from bankruptcy filings, including legal expenses, accounting expenses, and liquidation of assets at below-market value. Indirect costs include other financial distress costs, including employee turnover, reduced employee productivity, reduced product quality due to cost-cutting measures, reduction in credit provide by suppliers, loss of customers, and higher interest rates demanded by lenders.

Bankruptcy Reform Act of 1978 Enacted to speed up and streamline bankruptcy proceedings. This law represented a shift to a relative priority doctrine of creditors' claims.

bankruptcy A legal action initiated by a lender when a borrower fails to make a scheduled payment. A company can file for bankruptcy protection under Chapters 7 and 11 of the bankruptcy statutes; otherwise, the lender can seize assets held by the borrower.

basic earning power (BEP) ratio Calculated by dividing earnings before interest and taxes by total assets. This ratio shows the raw earning power of the firm's assets before the influence of taxes and leverage.

basis point Equal to 1/100 of a percentage point. For example, 0.25 percentage points are equal to 25 basis points. A decline in interest rates from 4.45% to 4.20% means that rates have fallen by 25 basis points.

Baumol model A model for establishing the firm's target cash balance that closely resembles the economic ordering quantity model used for inventory. The model assumes (1) that the firm uses cash at a steady, predictable rate, (2) that the firm's cash inflows from operations also occur at a steady, predictable rate, and (3) that its net cash outflows therefore also occur at a steady rate. The model balances the opportunity cost of holding cash against the transactions costs associated with replenishing the cash account.

behavioral finance A field of study that analyzes investor behavior as a result of psychological traits. It does not assume that investors necessarily behave rationally and instead focuses on irrational, but predictable, financial decisions.

benchmark company A leading competitor that is selected by a company for comparative purposes.

benchmarking When a firm compares its ratios to other leading (benchmark) companies in the same industry.

benefit corporation (B-Corp) Corporate form that expands directors' fiduciary responsibilities to include interests other than just shareholders.

best efforts arrangement A type of contract with an investment banker when issuing stock. In a best efforts sale, the investment banker is only committed to making every effort to sell the stock at the offering price. In this case, the issuing firm bears the risk that the new issue will not be fully subscribed.

beta risk The risk that an individual stock's beta (or an individual project's beta) contributes to a well-diversified portfolio. Also called market risk.

beta coefficient, b A measure of the amount of risk that an individual stock contributes to a well-diversified portfolio.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

bid quote (or bid price) Price at which investor is willing to buy a stock or other security.

binomial approach A method of determining an option's value by assuming that the underlying asset's value can change to only one of two values at the end of a time period. For example, the binomial method might assume that a stock's price can only go up by 15% or down by 10% during the next year.

binomial lattice Occurs when an underlying asset's value can change to only one of two values at the end of a time period. Changes in subsequent periods depend upon the changes in previous periods. The resulting path of possible values resembles a lattice.

bird-in-the-hand theory Assumes that investors value a dollar of dividends more highly than a dollar of expected capital gains, because a certain dividend is less risky than a possible capital gain. This theory implies that a high-dividend stock has a higher price and lower required return, all else held equal.

Black-Scholes option pricing model (OPM) A model to estimate the value of a call option. It is widely used by options traders.

board of trustees Group of community leaders who control a tax-exempt, charitable organization. Members of the board of trustees must have no direct economic interest in the organization.

bond A promissory note issued by a business or a governmental unit.

bond covenant Provisions in a bond indenture that cover such points as the conditions under which the issuer can pay off the bonds prior to maturity, the levels at which certain ratios must be maintained if the company is to issue additional debt, and restrictions against the payment of dividends unless earnings meet certain specifications. Also called a covenant or a restrictive covenant.

bond insurance Protects investors against default by the issuer and provides credit enhancement to the bond issue.

bond rating Reflects the probability that a bond will go into default. Bonds rated AAA have the least probability of defaulting.

bond spread The difference between the yield of a bond relative to another bond with less risk.

book value per share Common equity divided by the number of shares outstanding.

book value Values of assets, liabilities, or equity as reported on financial statements.

book-building Process of investment banker recording the number of shares each investor is willing to buy in an IPO.

branch of decision tree A possible path in a decision tree arising.

break-even analysis A form of sensitivity analysis that identifies the level of an input that produces an output of exactly zero. Often used to find the value of a project's input needed for the project to have an NPV of zero.

break-even point The level of unit sales at which costs equal revenues. Also called the operating break-even point.

breakup value A firm's value if its assets are sold off in pieces.

broker Person or organization that registers with the SEC to buy and sell stocks on behalf of clients. Brokers must also follow state and industry licensing and registration requirements.

brokerage firm A company that employs registered brokers to buy and sell stocks on behalf of clients.

broker-dealer A broker that also is registered so that it can buy and sell for itself when it acts as a market maker.

business risk The risk inherent in the operations of the firm, prior to the financing decision. Thus, business risk is the uncertainty inherent in future operating income or earnings before interest and taxes. Business risk is caused by many factors; two of the most important are sales variability and operating leverage.

bylaws Set of rules drawn up by the founders of the corporation to specify how it will be governed.

C

call option An option that allows the holder to buy the asset at some predetermined price within a specified period of time.

call premium The extra amount above the par value that a company must pay if it calls a bond that has a call provision. The premium generally declines over time.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

call protection Feature stating that a callable bond may not be called until a specified number of years after issue have passed. This is also known as a deferred call provision.

call provision Gives the issuing corporation the right to call the bonds for redemption. The call provision generally states that if the bonds are called then the company must pay the bondholders an amount greater than the par value, or a call premium. Most bonds contain a call provision.

callable bond Bond that gives the issuing corporation the right to call the bonds for redemption. The call provision generally states that if the bonds are called then the company must pay the bondholders an amount greater than the par value, or a call premium. Most bonds contain a call provision.

Capital Asset Pricing Model (CAPM) A model based on the proposition that any stock's required rate of return is equal to the risk-free rate of return plus a risk premium reflecting only the risk remaining after diversification. The CAPM equation is $r_i = r_{RF} + b_i(r_M - r_{RF})$.

capital budget Outlines the planned expenditures on fixed assets.

capital budgeting The whole process of analyzing projects and deciding whether they should be included in the planned expenditures on fixed assets.

capital components Sources of investor-supplied capital used to determine the weighted average cost of capital, including common stock, preferred stock, and long-term debt. Short-term debt is a capital component for those companies using it as a permanent source of financing.

capital gain (loss) The profit (loss) from the sale of a capital asset for more (less) than its purchase price. Long-term corporate capital gains are taxed at the corporation's regular income tax rate. Long-term individual capital gains are taxes at a lower rate than the individual ordinary income tax rate.

capital gains yield Results from changing prices and is calculated as $(P_1 - P_0)/P_0$, where P_0 is the beginning-of-period price and P_1 is the end-of-period price.

capital gains yield (on a bond) The rate of return due to a change in a bond's price. The total yield on a bond is equal to the sum of the current yield and the expected capital gains yield.

capital intensity ratio, $(A_0 * / S_0)$ The dollar amount of assets required to produce a dollar of sales, defined as the assets at Time 0 (A_0) divided by the sales at Time 0 (S_0). If all assets are used in operations (i.e., there are no short-term investments), the capital intensity ratio is the reciprocal of the total assets turnover ratio.

capital lease Covers the entire expected life of the equipment; does not provide for maintenance service, is not cancelable, and is fully amortized. Also called a financial lease.

capital market Capital markets are the financial markets for long-term debt and corporate stocks. The New York Stock Exchange is an example of a capital market.

Capital Market Line (CML) Shows the relationship between the expected return and standard deviation for the set of optimal portfolios: $\hat{r}_p = r_{RF} + [(\hat{r}_M - r_{RF})/\sigma_M]\sigma_p$

capital rationing Occurs when management places a constraint on the size of the firm's capital budget during a particular period.

capital requirement ratio (CR) Total net operating capital divided by sales. Measures how much total net operating must be tied up to generate a dollar of sales.

capital structure The manner in which a firm's assets are financed; that is, the right side of the balance sheet. Capital structure is normally expressed as the percentage of each type of capital used by the firm such as debt, preferred stock, and common equity.

capital structure decision Company's choice of a target capital structure, average maturity of its debt, and the specific types of financing it decides to use at any particular time.

capitalizing the lease Incorporating the lease provisions into the balance sheet by reporting the leased asset under fixed assets and reporting the present value of future lease payments as debt.

CAPM, Capital Asset Pricing Model A model based on the proposition that any stock's required rate of return is equal to the risk-free rate of return plus a risk premium reflecting only the risk remaining after diversification. The CAPM equation is $r_i = r_{RF} + b_i(r_M - r_{RF})$.

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

cash balance plan a type of defined benefits plan in which benefits are defined in terms of the cash balance in the employee's account rather than monthly salary.

cash budget A schedule showing net cash flows (receipts, disbursements), actual cash balances, and target cash balances for a firm over a specified period.

cash conversion cycle The length of time between the firm's actual cash expenditures on productive resources (materials and labor) and its own cash receipts from the sale of products (that is, the length of time between paying for labor and materials and collecting on receivables). Thus, the cash conversion cycle equals the length of time the firm has funds tied up in current assets.

cash discounts (in credit terms) A provision in credit terms: A percentage reduction in the sales price if the purchaser pays in cash before the end of the specified discount period. Otherwise, the full price is due at the end of the regular credit period. Also called discounts, cash discounts, or trade discounts.

CDO, collateralized debt obligation Created when large numbers of mortgages are bundled into pools to create new securities that are then sliced into tranches; the tranches are re-combined and re-divided into securities called CDOs.

CDS, credit default swap Derivative in which a counterparty pays if a specified debt instrument goes into default; similar to insurance on a bond.

Chapter 11 bankruptcy The 11th chapter of the bankruptcy statutes, regulates reorganization in a bankruptcy. Filed by a borrower to prevent a lender from filing a bankruptcy claim and seizing assets.

Chapter 7 bankruptcy The 7th chapter of the bankruptcy statutes, regulates liquidation in a bankruptcy. Filed by a borrower to prevent a lender from filing a bankruptcy claim and seizing assets.

characteristic line Obtained by regressing the historical returns on a particular stock against the historical returns on the general stock market. The slope of the characteristic line is the stock's beta, which measures the amount by which the stock's expected return increases for a given increase in the expected return on the market.

charitable contributions One way that not-for-profit businesses raise equity capital. Individuals and firms make these contributions for a variety of reasons including concern for the well-being of others, the recognition that accompanies large donations, and tax deductibility.

charter The legal document that is filed with the state to incorporate a company.

classified boards A board of directors with staggered terms. For example, a board with one-third of the seats filled each year and directors serving three-year terms.

classified stock Sometimes created by a firm to meet special needs and circumstances. Generally, when special classifications of stock are used, one type is designated "Class A," another as "Class B," and so on. For example, Class A might be entitled to receive dividends before dividends can be paid on Class B stock. Class B might have the exclusive right to vote.

cleanup clause A clause in a line of credit that requires the borrower to reduce the loan balance to zero at least once a year.

clearing (payment process) Occurs when: (1) A payer's bank verifies that the payer has sufficient funds. (2) The payer's bank receives confirmation (usually through the Federal Reserve) that it has sufficient funds. Clearing must occur before the payer's account and the payee's account can be settled.

clientele effect The attraction of companies with specific dividend policies to those investors whose needs are best served by those policies. Thus, companies with high dividends will have a clientele of investors with low marginal tax rates and strong desires for current income. Conversely, companies with low dividends will have a clientele of investors with high marginal tax rates and little need for current income.

cliff vesting All the options in a grant vest on the same date.

closely held corporation Refers to companies that are so small that their common stocks are not actively traded; they are owned by only a few people, usually the companies' managers.

coefficient of variation, CV Equal to the standard deviation divided by the expected return; it is a standardized risk measure that allows comparisons between investments having different expected returns and standard deviations.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

collateralized debt obligation (CDO) Created when large numbers of mortgages are bundled into pools to create new securities that are then sliced into tranches; the tranches are re-combined and re-divided into securities called CDOs.

collection policy The procedure for collecting accounts receivable. A change in collection policy will affect sales, days sales outstanding, bad debt losses, and the percentage of customers taking discounts.

collections float Float created while funds from customers' checks are being deposited and cleared through the check collection process.

combination lease Combines some aspects of both operating and financial leases. For example, a financial lease that contains a cancelation clause—normally associated with operating leases—is a combination lease.

commercial bank Financial intermediary whose primary purpose is to take deposits and make loans to businesses and individuals.

commercial paper Unsecured, short-term promissory notes of large firms, usually issued in denominations of $100,000 or more and having an interest rate somewhat below the prime rate.

commitment fee Fee paid by a borrower to a bank to establish a formal, committed line of credit even if borrower doesn't draw on the line of credit.

commodity futures Futures contracts that involve the sale or purchase of various commodities, including grains, oilseeds, livestock, meats, fiber, metals, and wood.

common equity (net worth) The cumulative sum of capital supplied by common stockholders—capital stock, paid-in capital, retained earnings, and (occasionally) certain reserves. Paid-in capital is the difference between the stock's par value and what stockholders paid when they bought newly issued shares.

common life (replacement chain) approach A method of comparing mutually exclusive projects that have unequal lives. Each project is replicated so that they will both terminate in a common year. If projects with lives of 3 years and 5 years are being evaluated, then the 3-year project would be replicated 5 times and the 5-year project replicated 3 times; thus, both projects would terminate in 15 years.

common pool problem Can happen in bankruptcy if the value of the borrowing firm is worth more as a going concern than in liquidation. Caused by individual creditors wishing to collect on their own debt even if it means borrower must sell vital assets needed to keep the company as a going concern. Leads to liquidation, which results in less total value to remaining creditors.

common size analysis Analysis in which all income statement items are divided by sales and all balance sheet items are divided by total assets. Thus, a common size income statement shows each item as a percentage of sales, and a common size balance sheet shows each item as a percentage of total assets.

comparative ratio analysis Compares a firm's own ratios to other leading companies in the same industry. This technique is also known as benchmarking.

compensating balance (CB) A minimum checking account balance that some banks require a firm to maintain to compensate the bank for services rendered or for making a loan; generally equal to 10%–20% of the loans outstanding.

competitive bids (security offerings) A security offering in which investment banks submit bids to the issuing company regarding the fees for underwriting the issuance. Occurs primarily with frequent debt offerings from large utilities.

composition Creditors voluntarily reduce their fixed claims on the debtor by accepting a lower principal amount, reducing the interest rate on the debt, accepting equity in place of debt, or some combination of these changes.

compound interest The interest that is earned (or charged) on interest as well as on principal.

compounding The process of finding the future value of a single payment or series of payments.

computer/telephone network A computer/telephone network that links buyers and sellers. It may or may not automatically execute trades.

conditional value at risk (CVaR) The average portfolio value (or loss) conditional upon the portfolio value being less than a specified threshold value (or threshold percentile). It can also be defined as the average NPV conditional upon the NPV being less than a specified threshold value (or threshold percentile). It is also called the expected shortfall (ES).

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

congeneric merger Involves firms that are interrelated but do not have identical lines of business. One example is Prudential's acquisition of Bache & Company.

conglomerate merger Occurs when unrelated enterprises combine, such as Mobil Oil and Montgomery Ward.

conservative approach (for short-term financing) Refers to using permanent capital to finance all permanent asset requirements as well as to meet some or all of the seasonal demands.

consol A type of perpetuity. Consols were originally bonds issued by England in the mid-1700s to consolidate past debt.

constant dividend growth model Formula for the present value of an infinite stream of constantly growing dividends. Sometimes called just the dividend growth model. Also called the Gordon model (or Gordon growth model) due to Myron J. Gordon.

constant growth model Formula for the present value of an infinite stream of constantly growing cash flows.

consumer credit markets Lending for consumer use, such as loans for autos, appliances, education, and vacations.

continuing value The present value of all free cash flows beyond the horizon date discounted back to the horizon date. Also called the horizon value (because it is at the horizon date) or the called the terminal value (because it is at the end of the explicit forecast period).

continuous probability distribution Probability distribution having an infinite number of possible outcomes. Often shown as a graph with outcomes on the x-axis having values that might range from $-\infty$ to $+\infty$ (although many probability distributions do not have an infinite range of possible outcomes). The values on the y-axis are a continuous curve that begin with a value of zero (or tangent to zero), are always positive, and end with a value of zero (or tangent to zero). Also, the area under this curve must be equal to 100% (this is a probability density function). Sometimes shown with cumulative probabilities on the y-axis (i.e., the probability that an outcome will be less than or equal to the value on the x-axis; this is a cumulative density function).

conversion price (P_c) The effective price per share of stock if conversion occurs; the par value of the convertible security divided by the conversion ratio.

conversion ratio (CR) The number of shares of common stock received upon conversion of one convertible security.

conversion value (C_t) The value of the stock that the investor would receive if conversion occurred; the market price per share times the conversion ratio.

convertible bond Bond that is convertible into shares of common stock, at a fixed price, at the option of the bondholder.

convertible currency A currency that can be traded in the international currency markets and can be exchanged at current market rates. Often called a hard currency.

convertible security Bonds or preferred stocks that can be exchanged for (converted into) common stock, under specific terms, at the option of the holder. Unlike the exercise of warrants, conversion of a convertible security does not provide additional capital to the issuer.

corporate governance The set of rules that control a company's behavior toward its directors, managers, employees, shareholders, creditors, customers, competitors, and community.

corporate risk The variability a project contributes to a corporation's stock returns; also called within-firm risk.

corporate alliance A cooperative deal that stops short of a merger but still allows firms to create combinations that focus on specific business lines that offer the most potential synergies. Also called a strategic alliance.

corporate bond Debt issued by corporations and exposed to default risk. Different corporate bonds have different levels of default risk, depending on the issuing company's characteristics and on the terms of the specific bond.

corporation A corporation is a legal entity created by a state. The corporation is separate and distinct from its owners and managers.

correlation The tendency of two variables to move together.

correlation coefficient, ρ (rho) A standardized measure of how two random variables covary. A correlation coefficient (ρ) of +1.0 means that the two

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

variables move up and down in perfect synchronization, whereas a coefficient of −1.0 means the variables always move in opposite directions. A correlation coefficient of zero suggests that the two variables are not related to one another; that is, they are independent.

cost of common stock, r_s A firm's cost to provide r_s, the return required by the firm's common stockholders.

cost of debt after taxes, $(1-T)r_d$ A company's after-tax cost of providing the required rate of return on debt.

cost of equity The price of using equity capital.

cost of new external common equity, r_e A project financed with external equity must earn a higher rate of return because it must cover the flotation costs. Thus, the cost of new common equity is higher than that of common equity raised internally by reinvesting earnings.

cost of preferred stock, r_{ps} The return required by the firm's preferred stockholders. The cost of preferred stock, r_{ps}, is the cost to the firm of issuing new preferred stock. For perpetual preferred, it is the preferred dividend, D_{ps}, divided by the net issuing price after flotation csots, $(1-F)P_{ps}$.

costly trade credit The extra credit taken from the end of the discount period to the end of the full credit period. It is costly because the payment to the seller is higher than it would have been if payment had been made during the discount period.

counterparty risk Risk that one of the two parties involved in a derivative position will not honor its financial obligations should an event call for a payment.

coupon interest rate Stated rate of interest on a bond; defined as the coupon payment divided by the par value.

coupon payment Dollar amount of interest paid to each bondholder on the interest payment dates.

Covenant Provisions in a bond indenture that cover such points as the conditions under which the issuer can pay off the bonds prior to maturity, the levels at which certain ratios must be maintained if the company is to issue additional debt, and restrictions against the payment of dividends unless earnings meet certain specifications. Also called a bond covenant or a restrictive covenant.

covered call option The situation when a person owns a share of stock and then writes a call option on the stock. If the option is exercised, then the writer is "covered" because the writer doesn't have to buy a share of stock in the market to be able to sell the share to the owner of the call option.

cramdown provision Reorganization plans that are mandated by the bankruptcy court and binding on all parties, which means all creditors must accept the plan even if they disagree.

credit default swap (CDS) Derivative in which a counterparty pays if a specified debt instrument goes into default; similar to insurance on a bond.

credit enhancement Enables a bond's rating to be upgraded to AAA when the issuer purchases bond insurance. The bond insurance company guarantees that bondholders will receive the promised interest and principal payments. Therefore, the bond carries the credit rating of the insurance company rather than that of the issuer.

credit period A provision in credit terms: The length of time for which credit is extended. For example, "net 30" means full payment is due in 30 days. If the credit period is lengthened then sales will generally increase, as will accounts receivable. This will increase the firm's financing needs and possibly increase bad debt losses. A shortening of the credit period will have the opposite effect.

credit policy The firm's policy on granting and collecting credit. There are four elements of credit policy: credit period, discounts, credit standards, and collection policy.

credit standards The financial strength and creditworthiness that qualifies a customer for a firm's regular credit terms.

credit terms Statement specifying the terms under which a customer may not be required to make immediate cash payment, including the discount percentage rate (if offered), discount period (if offered), and the credit period at which full payment is due. For example, "2/10, net 30" means that a purchaser can deduct 2% of the sales price by paying in cash within 10 days; otherwise, the full price is due in 30 days.

credit union Cooperative associations that take deposits from members and then make loans only to other members, generally for auto purchases, home-improvement loans, and home mortgages.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

cross rate The exchange rate between two non-U.S. currencies.

crossover rate The cost of capital at which the NPV profiles for two projects intersect. One project has a higher NPV below the crossover rate but the other project has a higher NPV above the crossover rate.

cumulative preferred dividends A protective feature on preferred stock that requires all past preferred dividends to be paid before any common dividends can be paid.

currency appreciation Occurs to a particular currency when it increases in value relative to another particular currency. For example, if the exchange rate of 1.0 dollar per euro changes to 1.1 dollars per euro, then the euro has appreciated against the dollar by 10%.

currency depreciation Occurs to a particular currency when it decreases in value relative to another particular currency. For example, if the exchange rate of 1.0 dollar per euro changes to 0.9 dollars per euro, then the euro has depreciated against the dollar by 10%.

currency swap A company makes a payment denoted in a specified currency to a counterparty and the counterparty make a payment to the company in a different currency—the two parties "swap" payments denoted in different currencies.

current ratio Indicates the extent to which current liabilities are covered by the most liquid current assets; it is found by subtracting inventories from current assets and then dividing this difference by current liabilities. It is also called the acid test ratio.

current yield (on a bond) The annual coupon payment divided by the current market price.

D

dark pool A type of trading venue that can be registered as an alternative trading system (ATS) with the SEC and is called a "dark pool" because it does not have to report any pre-trade quotes.

days sales outstanding (DSO) Used to appraise accounts receivable and indicates the length of time the firm must wait after making a sale before receiving cash. It is found by dividing receivables by average daily sales. Also called the average collection period and receivables conversion period.

DCF (discounted cash flow) analysis The method of determining today's value of a cash flow to be received in the future. Because a dollar in the future is worth less than a dollar today, the process of equating today's dollars with future dollars is called discounting. Also called the time value of money analysis. DCF analysis can be used to estimate a financial asset's value by finding the present value of the asset's expected cash flows when discounted at rate that reflects the asset's risk. This method can be applied to the cash flows from bonds, stocks, entire companies, and specific projects.

dealer market In a dealer market, a dealer holds an inventory of the security and makes a market by offering to buy or sell. Others who wish to buy or sell can see the offers made by the dealers and can contact the dealer of their choice to arrange a transaction.

debenture An unsecured bond; as such, it provides no lien against specific property as security for the obligation. Debenture holders are therefore general creditors whose claims are protected by property not otherwise pledged.

debt ratio The ratio of total debt provided by investor to total assets, it measures the percentage of funds provided by investors other than preferred or common shareholders. Also called the debt-to-assets ratio.

debt service requirements The total amount of principal and interest that must be paid on a bond issue.

debtor-in-possession (DIP) financing Provision in bankruptcy law making any additional funds borrowed for short-term liquidity purposes senior to all previous unsecured debt. This allows the borrowing firm to continue operations during the bankruptcy proceedings.

debt-to-assets ratio The ratio of total debt provided by investors to total assets, it measures the percentage of funds provided by investors other than preferred or common shareholders. Also called the debt ratio.

debt-to-equity ratio Ratio of total debt provided by investors divided by total equity.

decision node A place in a decision tree at which managers can make a decision based on the situation occurring at that point. Called a node because additional paths branch out, with each branch corresponding to the possible decisions.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

decision tree A form of project analysis in which future *possible* scenarios for cash flows are identified for each year in the project's life *and* in which managers can make decisions at future dates depending on the *actual* scenario occurring at that future date. It is called a decision tree because there are branches beginning at Year 0 (e.g., three possible scenarios) and because managers can make a decision at a future time (e.g., abandon the project or increase capacity, depending on the level of demand at that time), which leads to additional branches based on that decision.

declaration date The date on which a firm's directors issue a statement declaring a dividend. The dollar value of the declared payment is reported as a liability on the balance sheet and the retained earnings account is reduced by that amount.

default risk The risk that a borrower may not pay the interest and/or principal on a loan when it becomes due. If the issuer defaults, investors receive less than the promised return on the bond. Default risk is influenced by the financial strength of the issuer and also by the terms of the bond contract, especially whether collateral has been pledged to secure the bond. The greater the default risk, the higher the bond's yield to maturity.

default risk premium (DRP) The premium added to the real risk-free rate to compensate investors for the risk that a borrower may fail to pay the interest and/or principal on a loan when they become due.

defensive merger Occurs when the management of acquisition target seek out a friendly company to acquire their company.

deferred annuity An annuity with a fixed number of equal payments occurring at the end of each period. Also called an ordinary annuity.

deferred call Feature stating that a callable bond may not be called until a specified number of years after issue have passed. This is also known as call protection.

defined benefit (DB) retirement plan Retirement plan in which the sponsoring employer agrees to pay retirement benefits based on the employee's length of service, salary, or other factors; i.e., the benefits are defined by the plan.

defined contribution (DC) retirement plan Under this type of pension plan, employers agree to make specific payments into a retirement fund and retirees receive benefits that depend on the plan's investment success.

depreciation expense A noncash charge against tangible assets, such as buildings or machines. It is taken for the purpose of showing an asset's estimated dollar cost of the capital equipment used up in the production process.

derivatives Claims whose value depends on what happens to the value of some other asset. Futures and options are two important types of derivatives, and their values depend on what happens to the prices of other assets. Therefore, the value of a derivative security is derived from the value of an underlying real asset or other security.

detachable warrant A warrant that can be detached and traded separately from the underlying security. Most bonds with warrants have detachable warrants.

devaluation The lowering, by governmental action, of the price of its currency relative to another currency. For example, in 1967 the British pound was devalued from $2.80 per pound to $2.50 per pound.

development bond A tax-exempt bond sold by state and local governments whose proceeds are made available to corporations for specific uses deemed (by Congress) to be in the public interest.

direct quote When discussing exchange rates, the number of U.S. dollars required to purchase one unit of a foreign currency. For example, EUR/USD 1.20 is a direct quote meaning that the rate is 1.20 dollars per euro.

disbursement float Float created before checks written by a firm have cleared and been deducted from the firm's account; disbursement float causes the firm's own checkbook balance to be smaller than the balance on the bank's records.

discount bond Bond prices and interest rates are inversely related; that is, they tend to move in the opposite direction from one another. A fixed-rate bond will sell at par when its coupon interest rate is equal to the going rate of interest, r_d. When the going rate of interest is above the coupon rate, a fixed-rate bond will

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

sell at a "discount" below its par value. If current interest rates are below the coupon rate, a fixed-rate bond will sell at a "premium" above its par value.

discount interest Interest that is calculated on the face amount of a loan but is paid in advance.

discount on forward rate When it takes more units of a foreign currency to buy a dollar in the future. The value of the foreign currency is less in the forward market than in the spot market; hence, the forward rate is at a discount to the spot rate. If using indirect quotes, the foreign currency is at a discount if the forward indirect quote is greater than the spot rate. If using direct quotes, the foreign currency is at a discount if the forward indirect quote is less than the spot rate.

discount percentage (credit) A provision in credit terms: The percentage reduction in the sales price if the purchaser pays in cash before the end of the specified discount period. For example, "2/10" means a 2% discount if paid within 10 days. Otherwise, the full price is due at the end of the regular credit period.

discount period (credit) A provision in credit terms: The number of days a purchaser is given to make a payment and still get the discount. For example, "2/10" means a 2% discount if paid within 10 days, so 10 days is the discount period. Otherwise, the full price is due at the end of the regular credit period.

discounted cash flow (DCF) analysis The method of determining today's value of a cash flow to be received in the future. Because a dollar in the future is worth less than a dollar today, the process of equating today's dollars with future dollars is called discounting. Also called the time value of money analysis. DCF analysis can be used to estimate a financial asset's value by finding the present value of the asset's expected cash flows when discounted at a rate that reflects the asset's risk. This method can be applied to the cash flows from bonds, stocks, entire companies, and specific projects.

discounted payback period The number of years it takes a firm to recover its project investment based on discounted cash flows.

discounting The process of finding the present value of a single payment or series of payments.

discounts (in credit terms) A provision in credit terms: A percentage reduction in the sales price if the purchaser pays in cash before the end of the specified discount period. Otherwise, the full price is due at the end of the regular credit period. Also called "cash discounts" or "trade discounts."

discrete probability distribution Probability distribution having a finite number of outcomes. Often presented as a listing, chart, or graph showing all possible outcomes with a probability assigned to each outcome. This listing of outcomes and probabilities is a probability density function.

distribution policy Sets the level of cash distributions (the dollar amount) and the form of the distributions (dividends and stock repurchases).

distribution ratio Percentage of net income distributed to shareholders through cash dividends or stock repurchases.

diversifiable risk Refers to that part of a security's total risk associated with random events not affecting the market as a whole. This risk can be eliminated by proper diversification. Also known as company-specific risk.

diversification The reduction in risk due to holding a portfolio of assets that are not perfectly correlated.

divestiture The opposite of an acquisition. That is, a company sells a portion of its assets—often a whole division—to another firm or individual.

dividend capitalization method Method of estimating a stock's cost of equity as the sum of its expected dividend yield and constant growth rate. Often called the dividend growth approach. Sometimes called the dividend-yield-plus-growth-rate approach or the discounted cash flow (DCF) approach.

dividend growth approach Method of estimating a stock's cost of equity as the sum of its expected dividend yield and constant growth rate. Often called the dividend capitalization model. Sometimes called the dividend-yield-plus-growth-rate approach or the discounted cash flow (DCF) approach.

dividend growth model Formula for the present value of an infinite stream of constantly growing dividends. Sometimes called the constant dividend growth model. Also called the Gordon model (or Gordon growth model) due to Myron J. Gordon.

dividend irrelevance theory Holds that dividend policy has no effect on either the price of a firm's stock or its cost of capital.

dividend reinvestment plan (DRIP) Allows stockholders to automatically purchase shares of common stock of the

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. paying corporation in lieu of receiving cash dividends. There are two types of plans: One involves only stock that is already outstanding; the other involves newly issued stock. In the first type, the dividends of all participants are pooled and the stock is purchased on the open market. Participants benefit from lower transaction costs. In the second type, the company issues new shares to the participants. Thus, the company issues stock in lieu of the cash dividend.

dividend tax penalty Occurs if dividends are taxed more highly than capital gains.

dividend yield Defined as either the end-of-period dividend divided by the beginning-of-period price or as the ratio of the current dividend to the current price. Valuation formulas use the former definition.

divisional cost of capital The appropriate cost of capital to use when evaluating the typical project of a division or line of business. It may differ from the company's overall cost of capital if division's risk or debt capacity differs from those of the company.

Dodd-Frank Wall Street Reform and Consumer Protection Act Passed by Congress in 2010 to prevent financial crises similar to the ones triggering the great recession of 2007.

domestic currency The currency from a local perspective. For example, in the United States, the local perspective means the dollar is the home currency; in India, the local perspective means the home currency is the rupee. Also called the home currency.

due diligence A detailed investigation of a target of a potential acquisition, including financial statements, legal liabilities, etc.

DuPont equation A formula showing that the rate of return on equity can be found as the profit margin multiplied by the product of total assets turnover and the equity multiplier.

duration (bond) Measures the average number of years that a bond's PV of cash flows (coupons and principal payments) remains outstanding. If the term structure is flat and can only shift up or down, then duration also measures the percentage change in a bond's price due to a percentage change in interest rates.

E

earnings A firm's net income as reported on its income statement. It is also called accounting profit or profit.

EBITDA Earnings before interest, taxes, depreciation, and amortization.

EBITDA coverage ratio The sum of pre-tax earnings available to pay leases and debt obligations divided by the sum of lease and debt obligations. In practice, this is often defined as the sum of EBITDA and lease payments divided by the sum of lease payments, interest payments, and required principal payments.

ECN Electronic communications network. A type of alternative trading system that uses an automated trading platform and that publicly reports order book information in much the same way as a registered stock exchange.

economic life The number of years a project should be operated to maximize its net present value; often less than the maximum potential life.

economic ordering quantity (EOQ) The order quantity that minimizes the costs of ordering and carrying inventories.

Economic Value Added (EVA) A method used to measure a firm's true profitability. EVA is found by taking the firm's after-tax operating profit and subtracting the annual cost of all the capital a firm uses. If the firm generates a positive EVA, its management has created value for its shareholders. If the EVA is negative, management has destroyed shareholder value.

economies of scale Phenomenon in which larger companies can reduce costs, increase sales, or both.

effective (or equivalent) annual rate (EAR or EFF%) The effective annual rate is the rate that, under annual compounding, would have produced the same future value at the end of 1 year as was produced by more frequent compounding, say quarterly. If the compounding occurs annually, then the effective annual rate and the nominal rate are the same. If compounding occurs more frequently, then the effective annual rate is greater than the nominal rate.

efficiency ratios A set of ratios that measure how effectively a firm is managing its assets. Also called asset management ratios.

efficient frontier The set of efficient portfolios out of the full set of potential portfolios. On a graph, the efficient frontier constitutes the boundary line of the set of potential portfolios.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Efficient Markets Hypothesis (EMH) States (1) that stocks are always in equilibrium and (2) that it is impossible for an investor to consistently "beat the market" by getting a higher return than is justified by the stock's risk. The EMH assumes that all important information regarding a stock is reflected in the price of that stock.

efficient portfolio Provides the highest expected return for any specified level of risk. The efficient portfolio also provides the lowest degree of risk for any specified level of expected return.

embedded options Options that are a part of another project. Also called real options, managerial options, and strategic options.

embedded rate (for debt) The average coupon rate on a company's outstanding debt; also called the historical rate. Used in rate case hearings for public utilities but not for valuation.

Employee Retirement Income Security Act (ERISA) The basic federal law governing the structure and administration of corporate pension plans.

employee stock ownership plan (ESOP) A type of retirement plan in which employees own stock in the company.

engineering life of project The maximum potential life of a project; also called physical life. This can exceed the optimal economic life.

enterprise risk management (ERM) A process that includes risk identification, risk assessment, and risk responses. ERM requires the participation of all levels within an organization.

entity multiple For a group of comparable firms, the average ratio of the observed market entity value to a particular metric that applies to a whole firm, such as sales, EBITDA, number of subscribers, or any other metric that applies to the entity values of the target firm and the comparable firms.

entity valuation model Estimates the total value of a corporation rather than just the values of debt or stock.

entity value The total value of a corporation, including its common stock, preferred stock, and debt.

entrenchment Occurs when a company has such a weak board of directors and has such strong anti-takeover provisions in its corporate charter that senior managers feel there is little chance of being removed.

EOQ model The equation used to find the economic ordering quantity: $\text{EOQ} = \sqrt{[2(\text{F})(\text{S})]/[(\text{C})(\text{P})]}$, where F is the fixed cost per order, S is annual sales, C is the annual carrying cost expressed as a percentage of average inventory value, and P is the purchase price per unit of inventory.

EOQ range The range around the optimal ordering quantity that may be ordered without significantly affecting total inventory costs.

equilibrium The condition under which the intrinsic value of a security is equal to its price; also, when a security's expected return is equal to its required return. Also known as market equilibrium.

equity multiplier A set of ratios that measure how effectively a firm is managing its assets. Also called asset management ratios.

equity premium (RP_M) Expected market return minus the risk-free rate; also called market risk premium or equity risk premium.

equity risk premium (RP_M) Expected market return minus the risk-free rate; also called market risk premium or equity premium.

equity carve-out IPO in which a parent company creates a new publicly traded company from a subsidiary and sells some of the stock to the public. Parent companies typically retain at least 80% of the subsidiary's common stock to maintain control and to preserve their ability to file a consolidated tax return. Also called a partial public offering or a spin-out.

equivalent annual annuity (EAA) method Use to compare mutually exclusive projects with different lifespans. Convert the unequal annual cash flows of a project into a constant cash flow stream (i.e., an annuity) whose NPV is equal to the NPV of the initial stream. Do for both projects and compare the annuities.

ESOP (employee stock ownership plan) A type of retirement plan in which employees own stock in the company.

ETF Exchange-traded fund, which is a special type of mutual fund that allows investors to sell their shares at any time during normal trading hours. ETFs usually have very low management expenses.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

euro The currency used by nations in the European Monetary Union.

Eurobond Any bond sold in some country other than the one in whose currency the bond is denominated. Thus, a U.S. firm selling dollar bonds in Switzerland is selling Eurobonds.

Eurodollar A U.S. dollar on deposit in a foreign bank or a foreign branch of a U.S. bank. Eurodollars are used to conduct transactions throughout Europe and the rest of the world.

European option An option which may be exercised only at expiration. In contrast, an American option may be exercised on or before the expiration date.

event risk The chance that some sudden event will occur and increase the credit risk of a company, hence lowering the firm's bond rating and the value of its outstanding bonds. Some bonds reduce event risk by including a super poison put in the bond's covenant.

exchange rate Specifies the number of units of a given currency that can be purchased for one unit of another currency. For example, USD/JPY 80 means that 1 U.S. dollar can purchase 80 Japanese yen. Also called the foreign exchange rate, the FX rate, and the FOREX rate.

exchange rate risk Risk that a transaction in a foreign currency will be more costly than anticipated due to possible future fluctuations in exchange rates.

exchange-traded fund (ETF) A special type of mutual fund that allows investors to sell their shares at any time during normal trading hours. ETFs usually have very low management expenses.

ex-dividend date The date when the right to the dividend leaves the stock. This date was established by stockbrokers to avoid confusion, and it is two business days prior to the holder-of-record date. If the stock sale is made prior to the ex-dividend date, then the dividend is paid to the buyer; if the stock is bought on or after the ex-dividend date, the dividend is paid to the seller.

exercise price The price stated in the option contract at which the security can be bought (or sold). Also called the strike price.

exercise value Equal to payoff of the option if it is in-the-money or zero if it is not in-the-money. For a call option that is in the money, the exercise value is the current price of the stock (underlying the option) minus the strike price of the option.

expectations theory States that the slope of the yield curve depends on expectations about future inflation rates and interest rates. Thus, if the annual rate of inflation and future interest rates are expected to increase, then the yield curve will be upward sloping; the curve will be downward sloping if the annual rates are expected to decrease.

expected rate of return on a portfolio, $\hat{r}_p$ The rate of return expected on a portfolio given its current price and expected future cash flows.

expected rate of return, $\hat{r}_s$ The rate of return expected on a stock given its current price and expected future cash flows. If the stock is in equilibrium, the required rate of return will equal the expected rate of return.

expected return The mean of the probability distribution of returns.

expected shortfall (ES) The average portfolio value conditional upon the portfolio value being less than a specified threshold value (or threshold percentile). It can also be defined as the average NPV conditional upon the NPV being less than a specified threshold value (or threshold percentile). It is also called the conditional value at risk (CVaR).

expiration date Date after which an option may not be exercised.

extension A form of debt restructuring in which creditors postpone the dates of required interest or principal payments, or both.

externality The effect a project has on other parts of the firm or on the environment.

extra dividend A dividend paid, in addition to the regular dividend, when earnings permit. Firms with volatile earnings may have a low regular dividend that can be maintained even in years of low profit (or high capital investment) but is supplemented by an extra dividend when excess funds are available. Also called a special dividend.

F

fairness (in bankruptcy) The standard of fairness states that claims must be recognized in the order of their legal and contractual priority. In simpler terms, the reorganization must be fair to all parties.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

Fama-French three-factor model Includes one factor for the excess market return (the market return minus the risk-free rate), a second factor for size (defined as the return on a portfolio of small firms minus the return on a portfolio of big firms), and a third factor for the book-to-market effect (defined as the return on a portfolio of firms with a high book-to-market ratio minus the return on a portfolio of firms with a low book-to-market ratio).

FASB Statement 13 The Financial Accounting Standards Board statement that spells out the conditions under which a lease must be capitalized and the specific procedures to follow.

FASB Financial Accounting Standards Board.

feasibility (in bankruptcy) The standard of feasibility states that there must be a reasonably high probability of successful rehabilitation and profitable future operations.

feasible set Represents all portfolios that can be constructed from a given set of stocks; also known as the attainable set.

FIFO (first-in, first-out) The inventory accounting method that estimates production costs and the value of remaining inventory by assuming that the first items placed in inventory are the first ones used in production.

Financial Industry Regulatory Authority (FINRA) A private nonprofit organization that acts on behalf of investors by: (1) licensing brokers and (2) monitoring trading activities of brokers and brokerage firms.

financial security A claim that is standardized and regulated by the government.

financial analysis Set of tools for evaluating opportunities to exchange cash now for claims on future cash.

financial asset market Market for stocks, bonds, notes, mortgages, derivatives, and other financial instruments.

financial distress costs Incurred when a leveraged company's value or cash flow declines to such an extent that the probability of bankruptcy becomes imminent. Costs include employee turnover, reduced employee productivity, reduced product quality due to cost-cutting measures, reduction in credit provide by suppliers, loss of customers, and higher interest rates demanded by lenders.

financial engineering Use of option pricing and derivative pricing techniques to create and determine the value of a new financial security or to determine the value of a real option embedded in a project.

financial futures Provide for the purchase or sale of a financial asset at some time in the future, but at a price that is established today. Financial futures exist for Treasury bills, Treasury notes and bonds, certificates of deposit, Eurodollar deposits, foreign currencies, and stock indexes.

financial instrument A claim on a future cash flow.

financial intermediary Intermediary that buys securities with funds that it obtains by issuing its own securities. An example is a common stock mutual fund that buys common stocks with funds obtained by issuing shares in the mutual fund.

financial lease Covers the entire expected life of the equipment; does not provide for maintenance service, is not cancelable, and is fully amortized. Also called a capital lease.

financial leverage The extent to which a firm uses debt financing. It is also the magnifying effect that debt has on ROE and stockholder risk. Sometimes defined as the ratio of total assets to common equity, which is the factor by which ROA is scaled up to determine ROE.

financial markets Ways of connecting providers of cash today with users of cash by exchanging the cash now for claims on future cash.

financial merger A merger in which the companies will not be operated as a single unit and for which no operating economies are expected.

financial risk The risk added by the use of debt financing. Debt financing increases the variability of earnings before taxes (but after interest); thus, along with business risk, it contributes to the uncertainty of net income and earnings per share. Business risk plus financial risk equals total corporate risk.

financial service corporation A corporation that offers a wide range of financial services such as brokerage operations, insurance, and commercial banking.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

financing deficit The shortfall of spontaneous liabilities, planned change in external financing (total changes of debt, preferred stock, and common stock from the preliminary financing plan), and internal funds (net income less planned dividends) relative to additional assets required by the operating plan.

financing feedback Circularity created when additional debt causes additional interest expense, which reduces the addition to retained earnings, which in turn requires a higher level of debt, which causes still more interest expense, causing the cycle to be repeated.

financing surplus The excess of spontaneous liabilities, planned change in external financing (total changes of debt, preferred stock, and common stock from the preliminary financing plan), and internal funds (net income less planned dividends) relative to additional assets required by the operating plan.

fixed assets turnover ratio The ratio of sales to net fixed assets; it measures how effectively the firm uses its plant and equipment.

fixed exchange rate system The system in effect from the end of World War II until August 1971. Under the system, the U.S. dollar was linked to gold at the rate of $35 per ounce, and other currencies were then tied to the dollar.

flexibility option Permit a firm to alter operations depending on how conditions change during the life of the project, such as the ability to produce different products to match changing demand.

float Difference between the balance shown in a firm's (or individual's) checkbook and the balance on the bank's records.

floating exchange rates Exchange rates that change with market forces of supply and demand, having little or no government intervention.

floating-rate bond A bond whose coupon payment may vary over time. The coupon rate is usually linked to the rate on some other security, such as a Treasury security, or to some other rate, such as the prime rate or LIBOR.

flotation cost The commissions, legal expenses, fees, and any other costs that a company incurs when it issue new securities. Often expressed as F, the total dollar value of flotation costs expressed as a percentage of proceeds.

forecast horizon The last year in a cash flow forecast. Cash flows may grow unevenly during the forecast period, but are assumed to grow at a constant rate for all periods after the forecast horizon. Also called the horizon date or the terminal date because it is at the end of the explicit forecast period.

forecasted financial statements (FFS) method Approach to financial planning in which a company forecasts its complete set of financial statements to determine the value of operations and the additional external funding that may be needed. Many items on the income statement and balance sheets are assumed to increase proportionally with sales. As sales increase, these items that are tied to sales also increase, and the values of these items for a particular year are estimated as percentages of the forecasted sales for that year.

foreign bond A bond sold by a foreign borrower but denominated in the currency of the country in which the issue is sold. Thus, a U.S. firm selling bonds denominated in Swiss francs in Switzerland is selling foreign bonds.

foreign currency Any currency other than the home (or domestic) currency. For example, from a perspective in the United States, all currencies other than the dollar are foreign currencies.

foreign exchange (FX) risk The risk that a change in a currency exchange rate might adversely affect a company.

foreign exchange rate Specifies the number of units of a given currency that can be purchased for one unit of another currency. For example, USD/JPY 80 means that 1 U.S. dollar can purchase 80 Japanese yen. Also called the exchange rate, the FX rate, and the FOREX rate.

foreign trade balance Level of imports relative to exports. A deficit occurs when businesses and individuals in the United States import more goods from foreign countries than are exported. A surplus occurs when exports are greater than imports.

FOREX rate Specifies the number of units of a given currency that can be purchased for one unit of another currency. For example, USD/JPY 80 means that 1 U.S.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

dollar can purchase 80 Japanese yen. Also called the exchange rate, the foreign exchange rate, and the FX rate.

forward contract A contract to buy or sell some item at some time in the future at a price established when the contract is entered into.

forward exchange rate The foreign exchange rate for exchange (delivery) at some agreed-upon future date, which is usually 30, 90, or 180 days from the day the transaction is negotiated.

founders' shares Stock owned by the firm's founders that have sole voting rights but restricted dividends for a specified number of years.

fraudulent conveyance (in bankruptcy) Provision in bankruptcy law to protect creditors from unjustified transfers of property by a firm in financial distress, such as selling assets at low prices to a firm's stockholder.

free cash flow valuation model Defines the total value of a company as the present value of its expected free cash flows discounted at the weighted average cost of capital (i.e., the value of operations) plus the value of nonoperating assets such as T-bills.

free cash flow (FCF) The cash flow actually available for distribution to all investors (shareholders and creditors) after the company has made all investments in fixed assets and working capital necessary to sustain ongoing operations. Defined as net operating profit after taxes (NOPAT) minus the investment in total net operating capital.

free trade credit Credit a purchaser receives during the discount period. If the purchaser pays after the discount period, the purchase must make a higher payment.

friendly merger Occurs when the target company's management agrees to the merger and recommends that shareholders approve the deal.

fully funded pension plan The present value of all expected retirement benefits is equal to assets on hand.

fund capital Not-for-profit business equivalent of equity capital. It consists of retained profits and charitable contributions.

fundamental beta Incorporates adjustments to historical beta that address impact of current variables such as operating leverage, financial leverage, and sales volatility.

fundamental value or price Value or price that incorporates all relevant information regarding expected future cash flows and risk.

funding strategy Necessary for a defined benefit plan and involves two decisions: how fast should any unfunded liability be reduced and what rate of return should be assumed in the actuarial calculations.

future value of annuity (FVA) The future value of a stream of annuity payments.

future value (FV) The value that a payment (or series of payments) will grow to at a future date.

futures contract A derivative contract in which one party agrees to purchase something at a predetermined price and in which the second party agrees to sell the same item at the same price. In contrast to a forward contract, the two parties must settle up each day as the price of the futures contract changes, a process called marking-to-market.

futures market For assets whose delivery is at some future date, such as 6 months or a year into the future.

FVA_N The future value of a stream of annuity payments, where N is the number of payments of the annuity.

$FVIFA_{I,N}$ The future value interest factor for an ordinary annuity of N periodic payments paying I percent interest per period.

$FVIF_{I,N}$ The future value interest factor for a lump sum left in an account for N periods paying I percent interest per period.

FV_N The future value of an initial single cash flow, where N is the number of periods the initial cash flow is compounded.

FX rate Specifies the number of units of a given currency that can be purchased for one unit of another currency. For example, USD/JPY 80 means that 1 U.S. dollar can purchase 80 Japanese yen. Also called the exchange rate, the foreign exchange rate, and the FOREX rate.

G

GAAP (Generally Accepted Accounting Principles) A set of standards for financial reporting established by the accounting profession.

GASB (Government Accounting Standards Board) Promulgates standards for issues pertaining to governmental entities.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

general obligation bonds Type of municipal bonds that are secured by the full faith and credit of a government unit; that is, backed by the full taxing authority of the issuer.

general partner General partners in a limited partnership have unlimited liability and control of decisions made by the partnership.

Glass-Steagall Act Passed in 1933 by Congress with the intent of preventing another great depression. It was fully repealed in 1999.

global corporation A corporation that operates in an integrated fashion in more than one country. Also called multinational corporation, multinational enterprise, and transnational corporation.

going public The act of selling stock to the public at large by a closely held corporation or its principal stockholders.

going interest rate The annual rate of interest stated in a contract, quoted for a security, or reported by the press. It is also called the market interest rate, the quoted rate, and the nominal annual interest rate.

going private Transaction in which the entire equity of a publicly held firm is purchased by a small group of investors, ending public trading of the stock.

golden parachute A payment made to executives who are forced out when a merger takes place.

goodwill An accounting intangible asset created when a company acquires another company but pays more than the assets are worth. The difference is called goodwill.

Gordon model Formula for the present value of an infinite stream of constantly growing dividends, named after Myron J. Gordon. Also called the Gordon growth model or the constant dividend growth model.

greenmail Targeted share repurchases that occur when a company buys back stock from a potential acquirer at a higher than fair-market price. In return, the potential acquirer agrees not to attempt to take over the company.

gross profit margin Ratio of gross profit (sales minus cost of goods sold) divided by sales.

growing annuity A series of payments that grow at a constant rate. Although an annuity payment is constant, the expression "growing annuity" is widely used.

growth option Occurs if an investment creates the opportunity to make other potentially profitable investments that would not otherwise be possible, including options to expand output, to enter a new geographical market, and to introduce complementary products or successive generations of products.

growth rate (g, g_L, or $g_{t,t+1}$) Growth rate of sales, free cash flows, or any other specified item. The rate can be over the next period (g), can be the long-term constant rate for all future periods (g_L), or can be from period t to period t + 1 ($g_{t,t+1}$).

GSE (government-sponsored enterprise) debt Debt issued by government-sponsored enterprises (GSEs) such as the Tennessee Valley Authority or the Small Business Administration; not officially backed by the full faith and credit of the U.S. government.

guideline lease Meets all of the Internal Revenue Service (IRS) requirements for a genuine lease. If a lease meets the IRS guidelines, the IRS allows the lessor to deduct the asset's depreciation and allows the lessee to deduct the lease payments. Also called a tax-oriented lease.

H

Hamada equation Shows the effect of debt on the beta coefficient—increases in debt increase beta, and decreases in debt reduce beta:
$b = b_U[1 + (1–T)(D/S)] = b/[1 + (1–T)(w_d/w_s)]$.

hard currency A currency that can be traded in the international currency markets and can be exchanged at current market rates. Often called a convertible currency.

hedge fund Raises money from institutional investors and a relatively small number of high net-worth individuals, then engages in a variety of investment activities.

hedge portfolio A portfolio, usually consisting of a call option and shares of stock, that will have a constant payoff at expiration no matter what the stock price is at expiration.

hedging A risk management technique in which a company can reduce or eliminate its exposure to a source of risk through the use of derivatives.

herding behavior Occurs when groups of investors emulate other successful investors and chase asset

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

classes that are doing well. Also occurs when analysts go along with other analysts rather than state their true opinions.

high-frequency trading (HFT) Occurs when a trader buys (or sells) stock and then immediately sells (or buys) the stock, usually within milliseconds. Unlike broker–dealer internalization, high-frequency traders do not provide any infrastructure or other direct service for other buyers and sellers.

historical beta Beta as estimated using historical data for the past returns on the stock and market portfolio. Often estimated by a regression with the stock's returns (or return in excess of the risk-free rate) on the y-axis and the market's returns (or excess returns) on the x-axis.

historical rate (for debt) The average coupon rate on a company's outstanding debt; also called the embedded rate. Used in rate case hearings for public utilities but not for valuation.

holder-of-record date If a company lists the stockholder as an owner on the holder-of-record date, then the stockholder receives the dividend.

holding company A corporation formed for the sole purpose of owning stocks in other companies. A holding company differs from a stock mutual fund in that holding companies own sufficient stock in their operating companies to exercise effective working control.

holdout problem (in bankruptcy) Occurs in informal bankruptcy reorganizations when all involved parties do not agree to the voluntary plan. Holdouts are usually made by creditors in an effort to receive full payment on claims.

home currency The currency from a local perspective. For example, in the United States, the local perspective means the dollar is the home currency; in India, the local perspective means the home currency is the rupee. Also called the domestic currency.

horizon value The present value of all free cash flows beyond the horizon date discounted back to the horizon date. Also called the terminal value (because it is at the end of the explicit forecast period) or the continuing value (because it is the value if operations continue to be used rather than be liquidated).

horizon date The last year in a cash flow forecast. Cash flows may grow unevenly during the forecast period, but are assumed to grow at a constant rate for all periods after the horizon date. Also called the forecast horizon or the terminal date because it is at the end of the explicit forecast period.

horizontal merger A merger between two companies in the same line of business.

hostile merger Occurs when the management of the target company resists the offer.

hurdle rate The rate used to discount a project's cash flows after taking into consideration firm's overall cost of capital, the divisional cost of capital, and any additional subjective risk assessments for the particular project, including its impact on the firm's debt capacity. Also called the project cost of capital and the risk-adjusted cost of capital.

I

improper accumulation The retention of earnings by a business for the purpose of enabling stockholders to avoid personal income taxes on dividends.

income bond Pays interest only if the interest is earned. These securities cannot bankrupt a company, but from an investor's standpoint, they are riskier than "regular" bonds.

income statement Summarizes the firm's revenues and expenses over an accounting period. Net sales are shown at the top of each statement, after which various costs, including income taxes, are subtracted to obtain the net income available to common stockholders. The bottom of the statement reports earnings and dividends per share.

incremental cash flow Those cash flows that arise solely from the asset that is being evaluated. Equal to the cash flows of the company with the project minus the cash flows without the project.

indentures A legal document that spells out the rights of both bondholders and the issuing corporation.

independent projects Projects that can be accepted or rejected individually.

indexed bond The interest rate of such a bond is based on an inflation index such as the consumer price index (CPI), so the interest paid rises automatically when the inflation rate rises, thus protecting the bondholders against inflation. The final principal

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). payment is also linked to inflation. Also called a purchasing power bond.

indifference curve The risk–return trade-off function for a particular investor; reflects that investor's attitude toward risk. An investor would be indifferent between any pair of assets on the same indifference curve. In risk–return space, the greater the slope of the indifference curve, the greater is the investor's risk aversion.

indirect quote When discussing exchange rates, the number of units of foreign currency that can be purchased for one unit of home currency. For example, from the U.S. perspective, USD/JPN 80 is an indirect quote meaning that the rate is 80 yen per dollar.

inflation premium (IP) The premium added to the real risk-free rate of interest to compensate for the expected loss of purchasing power. The inflation premium is the average rate of inflation expected over the life of the security.

informal debt restructuring An agreement between a troubled firm and its creditors to change existing debt terms. An extension postpones the required payment date; a composition is a reduction in creditor claims.

information content hypothesis (dividends) A theory that holds that investors regard dividend changes as "signals" of management forecasts. Thus, when dividends are raised, this is viewed by investors as recognition by management of future earnings increases. Therefore, if a firm's stock price increases with a dividend increase, the reason may not be investor preference for dividends but rather expectations of higher future earnings. Conversely, a dividend reduction may signal that management is forecasting poor earnings in the future. Also called the dividend signaling hypothesis.

initial public offering (IPO) Occurs when a closely held corporation or its principal stockholders sell stock to the public at large.

I_{NOM} The nominal, or quoted, annual interest rate. This is the rate used in a time line if the cash flows occur annually. If cash flows occur more frequently, it should not be used in a time line.

inside directors Board members who hold managerial positions within the company, such as the CFO.

insiders The officers, directors, and employees of a publicly traded company. Insiders at privately held companies also include major stockholders.

interest coverage ratio Also called the times-interest-earned (TIE) ratio; determined by dividing earnings before interest and taxes by the interest expense.

interest rate The price of using debt.

interest rate parity Holds that investing in a domestic risk-free bond should provide the same return as converting cash into a foreign currency while simultaneously purchasing a risk-free bond in the foreign country and taking a position in a forward contract to convert the bond payment from the foreign into the original domestic currency. Otherwise, investors would be able engage in arbitrage.

interest rate risk Arises from the fact that bond prices decline when interest rates rise. Under these circumstances, selling a bond prior to maturity will result in a capital loss; the longer the term to maturity, the larger the loss.

interest rate swap A company makes a floating rate payment to a counterparty (usually based on the current LIBOR rate) and the counterparty makes a fixed payment to the company, or vice versa. In other words, the company and the counterparty swap fixed payments for floating rate payments.

interest tax shield ($V_{Tax\ shield}$) Present value of all expected future annual tax savings due to deductibility of interest expenses.

interlocking boards of directors Occur when the CEO of Company A sits on the board of Company B while B's CEO sits on A's board.

internal rate of return (IRR) method The discount rate that equates the present value of the expected future cash inflows and outflows. IRR measures the rate of return on a project, but it assumes that all cash flows can be reinvested at the IRR rate.

internalization A pair of trades in which a broker–dealer is the counterparty for both clients—the broker-dealer buys from one client and sells to the other.

international bond Any bond sold outside of the country of the borrower. There are two types of international bonds: Eurobonds and foreign bonds.

interstate public offering Occurs when securities are registered for sale in more than one state; regulated by the SEC unless it is a very small offering.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

in-the-money option An option that would have a positive payoff if exercised immediately. For example, a call option is in-the-money if the stock price is greater than the strike price.

intrinsic value or price Value or price that incorporates all relevant information regarding expected future cash flows and risk.

inventory conversion period The average length of time to convert materials into finished goods and then to sell them; calculated by dividing total inventory by daily costs of goods sold.

inventory turnover ratio Cost of goods sold (which includes depreciation) divided by inventories.

inverse floater Floating rate security with interest payments that move counter to market rates. If the market interest rate (usually LIBOR) goes up, the floating rate payment goes down, and vice versa if the market interest rate falls.

inverted (abnormal) yield curve A downward-sloping yield curve. Also called an abnormal yield curve.

investment bank A firm that assists in the design of an issuing firm's corporate securities and in the sale of the new securities to investors in the primary market.

investment timing option Gives companies the option to delay a project rather than implement it immediately. This option to wait allows a company to reduce the uncertainty of market conditions before it decides to implement the project.

investment-grade bond Securities with ratings of Baa/BBB or above.

investment strategy Deals with the question of how the pension assets portfolio should be structured given the assumed actuarial rate of return.

investor-supplied capital Total amount of short-term debt, long-term debt, preferred stock, and total common equity shown on a balance sheet. It is the amount of financing that investors have provided to a company. It also called total investor-supplied capital.

investor-supplied operating capital The total amount of short-term debt, long-term debt, preferred stock, and total common equity shown on a balance sheet, less the amount of short-term investments shown on the balance sheet. It is the amount of financing used in operations that investors have provided to a company. It also called total investor-supplied operating capital. It is also equal to the total amount of net operating capital.

involuntary petition (in bankruptcy) Filing by creditor of petition in bankruptcy court.

irregular cash flow stream A stream of cash flows that cannot be represented by an annuity.

J

Jensen's alpha Measures the vertical distance of a portfolio's return above or below the Security Market Line; first suggested by Professor Michael Jensen, it became popular because of its ease of calculation. It measures the average return that cannot be explained by the CAPM.

joint venture Involves the joining together of parts of companies to accomplish specific, limited objectives. Joint ventures are controlled by the combined management of the two (or more) parent companies.

junk bond High-risk, high-yield bond issued to finance leveraged buyouts, mergers, or troubled companies.

just-in-time (JIT) inventory system Process in which delivery of components is tied to the speed of the assembly line, with delivery to production facility occurring just before the parts are needed. Reduces the need to carry large inventories, but requires a great deal of coordination between the manufacturer and its suppliers.

K

keiretsus Form of corporate organization in Japan having combinations of companies with cross-ownership of stock among the member companies.

L

lead underwriter Investment bank that sets up a security offering and forms a syndicate to help sell it. Also called managing underwriter.

lessee The party leasing the property.

lessor The party receiving the payments from the lease (that is, the owner of the property).

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

leveraged buyout (LBO) A transaction in which a firm's publicly owned stock is acquired in a mostly debt-financed tender offer, resulting in a privately owned, highly leveraged firm. Often, the firm's own management initiates the LBO.

leveraged lease The lessor borrows a portion of the funds needed to buy the equipment to be leased.

liabilities-to-assets ratio The ratio of total liabilities to total assets, it measures the percentage of funds provided by other than preferred and common shareholders.

LIBOR (London Interbank Offered Rate) Rate that U.K. banks charge one another. Many financial contracts have rates based on LIBOR, such as LIBOR + 2%.

lien The right of a creditor to claim a specific asset in the event of default on the debt.

life insurance company Takes premiums from customers, invests these funds in stocks, bonds, real estate, and mortgages, and then makes payments to beneficiaries.

LIFO (last-in, first-out) The inventory accounting method that estimates production costs and the value of remaining inventory by assuming that the last items (i.e., the most recent) placed in inventory are the first ones used in production.

limit order Order sent to a broker in which the buyer or seller specifies limits with respect to the bid or ask price and duration for which the order is in effect.

limited liability corporation (LLC) Combines the limited liability advantage of a corporation with the tax advantages of a partnership.

limited liability partnership (LLP) Combines the tax advantages of a partnership with the limited liability advantage of a corporation.

limited partners Limited partners' liabilities, investment returns, and control are limited in a limited partnership.

limited partnership A partnership in which limited partners' liabilities, investment returns, and control are limited; general partners have unlimited liability and control.

line of credit An arrangement in which a bank agrees to lend up to a specified maximum amount of funds during a designated period. Often has a cleanup clause requiring the balance to be zero at least once a year.

linear programming for capital budgeting Technique to find maximum (or minimum) value of a linear objective function subject to linear constraints. Can be used to select the optimal mix of projects if constraints preclude accepting all NPV project.

liquid asset One that trades in an active market, so it can be converted quickly to cash at the going market price.

liquidation (in bankruptcy) The sale of the assets of a firm and the distribution of the proceeds to the creditors and owners in a specific priority. Can be informal or formal (via Chapter 7 of the bankruptcy code).

liquidity (corporation) Liquidity refers to a firm's cash and marketable securities position and to its ability to meet maturing obligations.

liquidity (security) The degree to which a security can be quickly sold at its "fair" value. Active markets provide liquidity.

liquidity premium (LP) A liquidity premium is added to the real risk-free rate of interest, in addition to other premiums, if a security is not liquid.

liquidity ratio A ratio that shows the relationship of a firm's cash and other current assets to its current liabilities.

listed stock A company's stock that an SEC-registered stock exchange accepts for listing after the company has registered with the SEC to have its stock traded publicly. A company can be listed on only one exchange, but can be traded on many.

lockbox system A cash management tool in which incoming checks for a firm are sent to post office boxes rather than to corporate headquarters. Several times a day, a local bank will collect the contents of the lockbox and deposit the checks into the company's local account.

London Interbank Offered Rate (LIBOR) Rate that U.K. banks charge one another. Many financial contracts have rates based on LIBOR, such as LIBOR + 2%.

long hedges Obligates the party to purchase the underlying asset at a predetermined price, providing protection against price increases. For example, a bread

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

manufacturer might go long in wheat to protect itself from increases in wheat prices.

Long-Term Equity AnticiPation Security (LEAPS) An option with an expiration date that is longer than that of a typical option. LEAPS can have up to 3 years before expiring.

loss aversion A behavioral phenomenon occurring when investors dislike a loss more than they like a gain of the same amount. For example, an investor dislikes a loss of $100 more than a gain of $100.

low-regular-dividend-plus-extras policy Dividend policy in which a company announces a low regular dividend that it is sure can be maintained; if extra funds are available, the company pays a specially designated extra dividend or repurchases shares of stock.

lumpy assets Those assets that cannot be acquired smoothly and instead require large, discrete additions. For example, an electric utility that is operating at full capacity cannot add a small amount of generating capacity, at least not economically.

M

MACRS (modified accelerated cost recovery system) An accelerated depreciation method in which property is assigned to a particular category (based on its useful life) for which the IRS has specified annual depreciation rates. These rates are applied to the basis, which is the acquisition cost.

make-whole call provision Allows a company to call a bond, but it must pay a call price that is essentially equal to the market value of a similar noncallable bond. This provides companies with an easy way to repurchase bonds as part of a financial restructuring, such as a merger.

managerial options Options that give opportunities to managers to respond to changing market conditions. Also called real options.

managing underwriter Investment bank that sets up a security offering and forms a syndicate to help sell it. Also called lead underwriter.

margin call Occurs when the stock prices falls and an investor had borrowed a percentage of the stock's price in order to buy the stock. The margin call requires the investor either to put up more money (i.e., pay of some of the borrowed money) or have their margined stock sold to pay off their loans.

margin requirement (for stock) The margin is the percentage of a stock's price that an investor has borrowed in order to purchase the stock. The Securities and Exchange Commission sets margin requirements, which is the maximum percentage of debt that can be used to purchase a stock.

margin requirement (futures) Amount that a futures exchange requires from an investor to ensure that the investor will not renege on the daily marking to market.

marginal cost of capital The cost of capital associated with the next dollar of investment. It may increase if new external funds have flotation costs or other incremental costs in addition to the required rate of return.

marginal rate (for debt) The required rate of return on new debt, which is the yield to maturity on existing debt and the coupon rate on new debt issued at par.

marginal tax rate The tax rate on the last unit of income.

market auction preferred stock Resets dividend rates every 7 weeks at an auction. Also called money market preferred stock.

market debt ratio The ratio of the market value of total debt provided by investor to the total market value of debt and equity. If the market value of debt is not available, then many analysts use the book value of debt as reported on the financial statements.

market equilibrium The condition under which the intrinsic value of a security is equal to its price; also, when a security's expected return is equal to its required return. Also known as equilibrium.

market interest rate The annual rate of interest stated in a contract, quoted for a security, or reported by the press. It is also called the going interest rate, the quoted rate, and the nominal annual interest rate.

market model A regression with a stock's returns on the y-axis and the market's returns on the x-axis.

market multiple method Used to estimate the value of a company. First identifies a sample of comparable firms and calculates for each comparable firm the ratio of its observed market value to a particular metric, which can be net income, earnings per share, sales, book value, number of subscribers, or any other metric that applies to the target firm and the comparable

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

firms. Then calculates the average ratio from the sample and multiplies the result by the metric of the target firm, resulting in the target firm's estimated value.

market order Order asking broker to trade at the market price.

market portfolio A portfolio consisting of all shares of all stocks.

market price The price of the most recent transaction as observed in a financial market. Sometimes the current quoted ask price is called the market price because the ask price is the one at which an investor could buy the asset.

market risk That part of a security's (or project's) total risk that cannot be eliminated by diversification; measured by the beta coefficient and often called beta risk. In the context of project analysis, it is the risk of the project as viewed by a well-diversified stockholder who owns many different stocks, which is the project's impact on the firm's beta coefficient.

market risk premium (RP_M) The difference between the expected return on the market and the risk-free rate. This is the extra rate of return that investors require to invest in the stock market rather than purchase risk-free securities. It is also called the equity premium or the equity risk premium.

market value Values of financial assets as determined in the markets—the price that a willing buyer will pay to a willing seller.

Market Value Added (MVA) The difference between the market value of the firm (that is, the sum of the market value of common equity, the market value of debt, and the market value of preferred stock) and the book value of the firm's common equity, debt, and preferred stock. If the book values of debt and preferred stock are equal to their market values, then MVA is also equal to the difference between the market value of equity and the amount of equity capital that investors supplied.

market value ratios Relate the firm's stock price to its earnings and book value per share.

market/book (M/B) ratio The stock price per share (i.e., the market value per share) divided by the book value per share; alternative, the total market value of equity divided by the total common equity reported on the balance sheet. Show how much current shareholders value the firm relative to the total cumulative amount of cash the firm has raised from shareholders either directly through stock issuances or indirectly by reinvesting net income rather than paying it all out as dividends.

marketable securities Can be converted to cash on very short notice and provide at least a modest return.

maturity date The date when the bond's par value is repaid to the bondholder. Maturity dates generally range from 10 to 40 years from the time of issue.

maturity matching approach (for short-term financing) A policy that matches asset and liability maturities. It is also referred to as the self-liquidating approach.

maturity risk premium (MRP) The net effect upon a bond's yield due to interest rate risk and reinvestment risk. Interest rate risk seems to dominate, because investors usually require a higher yield for bonds with longer maturities.

merger The joining of two firms to form a single firm.

Miller model Introduces the effect of personal taxes into the valuation of a levered firm, which reduces the advantage of corporate debt financing: $V_L = V_U + \left[1 - \frac{(1-T_c)(1-T_s)}{(1-T_d)}\right]D$

MM Proposition I States that if there are no taxes, then $V_L = V_U = EBIT/r_{sU}$. Since both EBIT and r_{sU} are constant, firm value is also constant and capital structure is irrelevant. If there are corporate taxes, states that $V_L = V_U + TD$. Thus, firm value increases with leverage and the optimal capital structure is virtually all debt.

MM Proposition II States that if there are no taxes, then the required return on stock increases so that the WACC remains constant: $r_{sL} = r_{sU} + (r_{sU} - r_d)(D/S)$. If there are corporate taxes, states that the WACC falls as debt is added and that the required rate of return on stock is: $r_{sL} = r_{sU} + (r_{sU} - r_d)(1-T)(D/S)$.

moderate policy (current assets) A policy under which operating current assets are not allowed to be excessively high nor restrictively low.

modified accelerated cost recovery system (MACRS) An accelerated depreciation method in which property is assigned to a particular category

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(based on its useful life) for which the IRS has specified annual depreciation rates. These rates are applied to the basis, which is the acquisition cost.

Modified Internal Rate of Return (MIRR) method Assumes that cash flows from all projects are reinvested at the cost of capital, not at the project's own IRR. This makes the modified internal rate of return a better indicator of a project's true profitability.

money market A financial market for debt securities with maturities of less than 1 year (short-term). The New York money market is the world's largest.

money market fund A mutual fund that invests in short-term debt instruments and offers investors check-writing privileges; thus, it amounts to an interest-bearing checking account.

money market preferred stock Resets dividend rates every 7 weeks at an auction. Also called market auction preferred stock.

Monte Carlo simulation analysis A risk analysis technique in which a computer is used to simulate probable future events and thus to estimate the likely profitability and risk of a project. Often called just simulation analysis. Can be applied to cash management systems as a means of estimating the appropriate target cash balance.

mortgage bond A bond for which a corporation pledges certain assets as security. All such bonds are written subject to an indenture.

mortgage market For loans on residential, agricultural, commercial, and industrial real estate.

multinational corporation A corporation that operates in an integrated fashion in more than one country. Also called global corporation, multinational enterprise, and transnational corporation.

multinational enterprise (MNE) A corporation that operates in an integrated fashion in more than one country. Also called global corporation, multinational corporation, and transnational corporation.

multiple IRRs Existence of more than one internal rate of return based on a project's cash flows and can occur when a project has nonnormal cash flows. In this situation, none of the calculated IRRs provide useful information.

multistage valuation model Approach to find the present value of cash flows that grow at a nonconstant rate for multiple periods before eventually beginning to grow at a constant growth rate for infinity. Is the sum of the present values of all cash flows during the forecast period plus the present value of the horizon value.

municipal bond Issued by state and local governments. The interest earned on most municipal bonds is exempt from federal taxes and also from state taxes if the holder is a resident of the issuing state.

municipal bond insurance An insurance company guarantees to pay the coupon and principal payments should the issuer of the bond (the municipality) default. This reduces the risk to investors who are willing to accept a lower coupon rate for an insured bond issue compared to an uninsured issue.

mutual fund A corporation that sells shares in the fund and uses the proceeds to buy stocks, long-term bonds, or short-term debt instruments. The resulting dividends, interest, and capital gains are distributed to the fund's shareholders after the deduction of operating expenses. Some funds specialize in certain types of securities, such as growth stocks, international stocks, or municipal bonds.

mutual savings bank Similar to S&Ls, but they operate primarily in the northeastern states.

mutually exclusive projects Projects that cannot be performed at the same time. A company could choose either Project 1 or Project 2, or it can reject both, but it cannot accept both projects.

N

naked option The situation when a person writes a call option on a stock but does not own shares of the stock. If the option is exercised, then the writer must buy a share of stock in the market to be able to sell the share to the owner of the call option.

NASDAQ Stock Market (NASDAQ) A registered U. S. stock exchange with the most company listings. NASDAQ stands for National Association of Securities Dealers Automated Quotations, although the exchange is not owned by the NASD and the NASD is now part of the Financial Industry Regulatory Authority (FINRA).

natural hedge A transaction between two counterparties where both parties' risks are reduced,

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

such as a farmer going short in wheat and a baker going long in wheat.

NBBO (National Best Bid and Offer) The overall best (highest) bid price and best (lowest) ask price (the price at which an investor offers to sell stock) from among all registered stock exchanges. The NBBO represents the best prices at which an investor could buy or sell on any registered exchange.

negotiated deals (security offerings) A security offering in which an investment bank negotiates with the issuing company regarding its fees for underwriting the issuance. Occurs with most stock and debt offerings.

net operating working capital (NOWC) Operating current assets minus operating current liabilities. Operating current assets are the current assets used to support operations, such as cash, accounts receivable, and inventory. They do not include short-term investments. Operating current liabilities are the current liabilities that are a natural consequence of the firm's operations, such as accounts payable and accruals. They do not include notes payable or any other short-term debt that charges interest.

net advantage to leasing (NAL) The dollar value of the lease to the lessee. It is the net present value of leasing minus the net present value of owning.

net cash flow The sum of net income plus noncash adjustments.

net float The difference between a firm's disbursement float and collections float.

net income Income as defined by Generally Accepted Accounting Principles (GAAP). Also called net income, accounting profit, profit, or earnings.

net investment in operating capital The change in total net operating capital from the previous year, which represents the net amount that the company has spent on operating capital during the year.

net operating capital The sum of net operating working capital and operating long-term assets, such as net plant and equipment. Net operating capital is also called total net operating capital. It is also equal to the net amount of investor-supplied operating capital.

net operating profit after taxes (NOPAT) The amount of profit a company would generate if it had no debt and no financial assets.

net present value (NPV) method The present value of the project's expected future cash flows, discounted at the appropriate cost of capital. NPV is a direct measure of the value of the project to shareholders.

net present value (NPV) profile Graph showing a project's NPV on the y-axis for different costs of capital on the x-axis.

net profit margin Calculated by dividing net income by sales; gives the profit per dollar of sales. Also called the profit margin on sales or just the profit margin. Often denoted by M for margin.

net working capital Current assets minus current liabilities. Different from net *operating* working capital, because current assets and current liabilities may contain nonoperating accounts such as short-term investments and short-term loans.

net worth of shareholders Total assets minus liabilities and preferred stock, which is the value of common equity shown on a balance sheet.

new-issue bond Describes a bond that has been issued recently, usually within one month. Such bonds are actively traded, whereas bonds that have been issued further in the past often have very little trading because they are held in portfolios until maturity.

New York Stock Exchange (NYSE) Oldest registered stock exchange in the Unites States. NYSE is the largest exchange when measured by the market value of its listed stocks.

nominal annual interest rate The annual rate of interest stated in a contract, quoted for a security, or reported by the press. When used in a time line with annual cash flows, it is called I_{NOM}. When referring to debt, the nominal annual rate is called the required rate of return on debt, r_d. When used in the context of expected inflation, the nominal rate is the rate that actually is observed in financial markets and is often denoted by r_n (for nominal)—it is the rate you see, whereas expected inflation and the real rate (i.e., the one that would exist if there were no inflation) are not directly observable. In the context of project analysis, if net cash flows from a project include increases due to expected future inflation, then the cash flows should be discounted at the nominal cost of capital to estimate NPV, and the internal rate of return resulting should be compared with the nominal cost of capital., The nominal rate is

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

also called the going interest rate, the market interest rate, and the quoted interest rate.

nonconvertible currency A currency that cannot be traded freely in the international currency markets and cannot be exchanged at current market rates but must be exchanged at a rate set by the country's government. Often called a soft currency.

nonnormal cash flow projects Projects with cash flows that change signs more than once. For example, cash flow is negative at beginning of project, becomes positive, and then becomes negative again. Nonnormal cash flows can have multiple internal rates of return.

nonoperating assets Include investments in marketable securities and noncontrolling interests in the stock of other companies.

nonoperating current assets Short-term investments or any other current assets not used in operations.

nonpecuniary benefits Perks that are not actual cash payments, such as lavish offices, memberships at country clubs, corporate jets, and excessively large staffs.

non-tax-oriented lease Does not meet meets Internal Revenue Service (IRS) requirements for a genuine lease. Therefore, the lessee cannot deduct the full lease payment for tax purposes but instead can deduct depreciation and the implied interest portion of the lease payment.

NOPAT (net operating profit after taxes) The amount of profit a company would generate if it had no debt and no financial assets.

normal cash flow project A project with one or more cash outflows (costs) followed by a series of cash inflows. Note that the signs of the cash flows change only once, when they go from negative to positive (or from positive to negative).

normal distribution A widely used continuous probability distribution that resembles a bell-shaped curve.

normal yield curve When the yield curve slopes upward, it is said to be "normal," because it is like this most of the time.

not-for-profit corporation A tax-exempt charitable organization. The tax code defines a charitable organization as any corporation, community chest, fund, or foundation that is organized and operated exclusively for religious, charitable, scientific, public safety, literary, or educational purposes. This standard may be expanded to include an organization that provides health care services provided other requirements are met.

notional principal For interest rate swaps, the principal amount used by the swapped interest rates to determine the dollar value of swapped payments.

notional value For forward and futures contracts, the amount to be delivered under the contract's terms.

O

off-balance sheet financing A financing technique in which a firm uses partnerships and other arrangements to (in effect) borrow money while not reporting the liability on its balance sheet. For example, for many years neither leased assets nor the liabilities under lease contracts appeared on the lessees' balance sheets. To correct this problem, the Financial Accounting Standards Board issued FASB Statement 13.

offer price Price at which the investment banking syndicate sells stocks to investors in an IPO.

off-exchange transaction The purchase or sale of a stock or other security that is not executed through a registered exchange. Also called an over-the-counter trade.

official statement Contains information about municipal bond issues. It is prepared before the issue is brought to market.

on-the-run bond Describes a bond that has been issued recently, usually within one month. Such bonds are actively traded, whereas bonds that have been issued further in the past often have very little trading because they are held in portfolios until maturity.

open outcry auction A method of matching buyers and sellers in which the buyers and sellers are face-to-face, all stating a price at which they will buy or sell.

operating break-even point The level of unit sales at which costs equal revenues. Also called the break-even point.

operating capital The sum of net operating working capital and operating long-term assets, such as net

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

plant and equipment. Operating capital is also called net operating capital and total net operating capital. It is also equal to the net amount of investor-supplied operating capital.

operating company A company controlled by a holding company.

operating current assets The current assets used to support operations, such as cash, accounts receivable, and inventory. It does not include short-term investments.

operating current assets financing policy The way a firm chooses to finance permanent and temporary operating current assets.

operating current liabilities The current liabilities that are a natural consequence of the firm's operations, such as accounts payable and accruals. It does not include notes payable or any other short-term debt that charges interest.

operating lease Provides for both financing and maintenance. Generally, the operating lease contract is written for a period considerably shorter than the expected life of the leased equipment and contains a cancelation clause; sometimes called a service lease.

operating leverage The extent to which fixed costs are used in a firm's operations. If a high percentage of a firm's total costs are fixed costs, then the firm is said to have a high degree of operating leverage. Operating leverage is a measure of one element of business risk but does not include the second major element, sales variability.

operating merger Occurs when the operations of two companies are integrated with the expectation of obtaining synergistic gains. These may occur in response to economies of scale, management efficiency, or a host of other factors.

operating profit margin Ratio of earnings before interest and taxes divided by sales.

operating profitability ratio (OP) Net operating profit after taxes divided by sales. Measures how many dollars of operating profit are generated per dollar of sales.

opportunity cost A cash flow that a firm must forgo in order to accept a project. For example, if the project requires the use of a building that could otherwise be sold, then the market value of the building is an opportunity cost of the project.

opportunity cost rate The rate of return available on the best alternative investment of similar risk.

optimal capital budget Set of projects that maximizes the value of the firm.

optimal distribution policy The distribution policy that maximizes the value of the firm by choosing the optimal level and form of distributions (dividends and stock repurchases).

optimal portfolio The point at which the efficient set of portfolios—the efficient frontier—is just tangent to the investor's indifference curve. This point marks the highest level of satisfaction an investor can attain given the set of potential portfolios.

option A contract that gives its holder the right to buy or sell an asset at some predetermined price within a specified period of time.

option value (of project) Value of opportunities to modify a project after its implementation, including expansion, contraction, or delay. Also includes additional opportunities that a project provides to a firm, such as introduction of complementary product line.

order book A trading venue's record of all limit orders still in effect.

ordinary annuity An annuity with a fixed number of equal payments occurring at the end of each period. Also called a deferred annuity.

original issue discount (OID) bond In general, any bond originally offered at a price that is significantly below its par value.

original maturity A bond's number of years until maturity at the time it is issued.

out-of-the money option An option that would not have a positive payoff if exercised immediately. For example, a call option is out-of-the-money if the stock price is less than the strike price.

outside directors Board members who are not employed by the company and who have no other affiliations or financial interests in the company.

outsourcing The practice of purchasing components rather than making them in-house.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

outstanding bond Describes a bond that has not been issued within the past month or two. Such bonds usually are not actively traded because they often are held in portfolios until maturity.

overfunded pension plan The assets on hand exceed the present value of all expected retirement benefits.

oversubscribed (IPO) Occurs in IPO when investors wish to purchase more shares than are available. Investment bank will allocate shares to the investors.

over-the-counter (OTC) trade The purchase or sale of a stock or other security that is not executed through a registered exchange.

P

par value The nominal or face value of a stock or bond. The par value of a bond generally represents the amount of money that the firm borrows and promises to repay at some future date. The par value of a bond is often $1,000, but it can be $5,000 or more.

parent company Another name for a holding company. A parent company will often have control over many subsidiaries.

partial public offering IPO in which a parent company creates a new publicly traded company from a subsidiary and sells some of the stock to the public. Parent companies typically retain at least 80% of the subsidiary's common stock to maintain control and to preserve their ability to file a consolidated tax return. Also called an equity carve-out or a spin-out.

partnership A partnership exists when two or more persons associate to conduct a business.

payables deferral period (PDP) The average length of time between a firm's purchase of materials and labor and the payment of cash for them. It is calculated by dividing accounts payable by credit purchases per day (i.e., cost of goods sold ÷ 365).

payback period The number of years it takes a firm to recover its project investment. Payback does not capture a project's entire cash flow stream and is thus not the preferred evaluation method. Note, however, that the payback does measure a project's liquidity, so many firms use it as a risk measure.

payment date The date on which a firm actually pays a cash dividend to those owning the stock two business days prior to the holder of record date.

payment (PMT) Equal to the dollar amount of an equal or constant cash flow (an annuity).

payment-in-kind (PIK) bonds Don't pay cash coupons but pay coupons consisting of additional bonds (or a percentage of an additional bond).

payout ratio Percentage of net income paid as a cash dividend. Often denoted by POR.

pecking order theory (capital structure) A preferred "pecking order" of financing: (1) reinvested earnings, followed by (2) debt, and then (3) new common stock. This avoids a negative signal caused by investors assuming that managers have more complete information and will issue stock when it is overvalued.

pegged exchange rates Rates that are fixed against a major currency such as the U.S. dollar. Consequently, the values of the pegged currencies move together over time.

Pension Benefit Guarantee Corporation Established by ERISA to insure corporate defined benefits plans; PBGC steps in and takes over payments to retirees of bankrupt companies with underfunded pension plans.

pension fund Retirement plan funded completely or partially by a corporation or government agency.

percentage change analysis Analysis in which percentage changes for all income statement items and balance sheet accounts are calculated relative to the items' values in the base year. Shows how different items change over time.

percentage flotation cost (F) The total dollar value of flotation costs expressed as a percentage of proceeds. Flotation costs include commissions, legal expenses, fees, and any other costs that a company incurs when it issue new securities.

perfect hedge A hedge in which the gain or loss on the hedged transaction exactly offsets the loss or gain on the unhedged position.

periodic compounding When interest is compounded once per period. The period is usually some period other than a year.

periodic rate (I_{PER}) The rate charged by a lender or paid by a borrower each period. It can be a rate per year,

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

per 6-month period, per quarter, per month, per day, or per any other time interval (usually 1 year or less).

permanent net operating working capital The NOWC required when the economy is weak and seasonal sales are at their low point. Thus, this level of NOWC always requires financing and can be regarded as permanent.

permanent operating current assets The level of current assets required when the economy is weak and seasonal sales are at their low point. Thus, this level of current assets always requires financing and can be regarded as permanent.

perpetuity A series of payments of a fixed amount that continue indefinitely.

petition (in bankruptcy) Initiation of formal bankruptcy proceeds via filing with bankruptcy court. Can be initiated by creditor (an involuntary petition) or borrower (voluntary petition).

physical asset market Market for tangible or "real" assets like as wheat, autos, real estate, computers, and machinery.

physical life of project The maximum potential life of a project; also called engineering life. This can exceed the optimal economic life.

physical location exchanges Exchanges, such as the New York Stock Exchange, that facilitate trading of securities at a particular location.

PIPE Private placement of public equity. Occurs when a public company sells shares of its stock directly to an investor, such as an insurance company or a pension fund.

poison pills Shareholder rights provisions that allow existing shareholders in a company to purchase additional shares of stock at a lower-than-market value if a potential acquirer purchases a controlling stake in the company.

political risk Refers to the possibility of expropriation and the unanticipated restriction of cash flows to the parent by a foreign government.

pollution control bond A tax-exempt bond sold by state and local governments whose proceeds are made available to corporations for pollution control projects deemed (by Congress) to be in the public interest.

pooling of interests A method of accounting for a merger in which the consolidated balance sheet is constructed by simply adding together the balance sheets of the merged companies. This is no longer allowed.

portability A portable pension plan is one that the employee can carry from one employer to another.

portfolio A group of individual assets held in combination. An asset that would be relatively risky if held in isolation may have little or no risk if held in a well-diversified portfolio.

portfolio companies (in VC fund) Companies in which a venture capital fund invests, comprising the fund's portfolio of investments.

post-audit The final aspect of the capital budgeting process. The post-audit is a feedback process in which the actual results are compared with those predicted in the original capital budgeting analysis. The post-audit has several purposes, of which the most important are to improve forecasts and operations.

precautionary balance A cash balance held in reserve for random, unforeseen fluctuations in cash inflows and outflows.

preemptive right Gives the current shareholders the right to purchase any new shares issued in proportion to their current holdings. The preemptive right enables current owners to maintain their proportionate share of ownership and control of the business.

preemptive rights offering Occurs when a corporation sells a new issue of common stock to its existing stockholders. Each stockholder receives a certificate, called a stock purchase right, giving the stockholder the option to purchase a specified number of the new shares. The rights are issued in proportion to the amount of stock that each shareholder currently owns. Also called a just a rights offering.

preferred stock A hybrid security that is similar to bonds in some respects and to common stock in other respects. Preferred dividends are similar to interest payments on bonds in that they are fixed in amount and generally must be paid before common stock dividends can be paid. If the preferred dividend is not earned, the directors can omit it without throwing the company into bankruptcy.

preliminary prospectus A preliminary prospectus that may be distributed to potential buyers prior to approval of

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

the registration statement by the Securities and Exchange Commission. After the registration has become effective, the securities—accompanied by the prospectus—may be offered for sale. Also called a red herring.

premium bond Bond prices and interest rates are inversely related; that is, they tend to move in the opposite direction from one another. A fixed-rate bond will sell at par when its coupon interest rate is equal to the going rate of interest, r_d. When the going rate of interest is above the coupon rate, a fixed-rate bond will sell at a "discount" below its par value. If current interest rates are below the coupon rate, a fixed-rate bond will sell at a "premium" above its par value.

premium on forward rate When it takes fewer units of a foreign currency to buy a dollar in the future. The value of the foreign currency is greater in the forward market than in the spot market; hence, the forward rate is at a premium to the spot rate. If using indirect quotes, the foreign currency is at a premium if the forward indirect quote is less than the spot rate. If using direct quotes, the foreign currency is at a premium if the forward indirect quote is greater than the spot rate.

prepackaged bankruptcy (or pre-pack) A type of reorganization that combines the advantages of informal workouts and formal Chapter 11 reorganization.

present value of annuity, PVA The value today of a stream of annuity payments.

present value, PV The value today of a payment (or series of payments) that will be received in the future. It is also the beginning amount that will grow to some future value.

pre-tax earnings or pre-tax income The amount of earnings (or income) that is subject to taxes. It is also equal to earnings before interest and taxes (EBIT) less the interest expense. It is sometimes called earnings before taxes (EBT)

price improvement Occurs when a broker's client gets a better deal than the posted NBBO quotes would indicate.

price/cash flow ratio Calculated by dividing price per share by cash flow per share, where cash flow is defined as net income plus depreciation. This shows how much investors are willing to pay per dollar of cash flow.

price/earnings (P/E) ratio Calculated by dividing price per share by earnings per share. This shows how much investors are willing to pay per dollar of reported profits.

price/EBITDA ratio The ratio of price per share divided by per share earnings before interest, depreciation, and amortization.

primary market Markets in which newly issued securities are sold for the first time, including IPOs and seasoned offerings.

prime rate Published by a bank as the rate it charges its strongest customers. However, very large and strong customers often can borrow at a lower rate.

principal (agency relationships) A person or organization to which has delegated decision-making authority to an agent, usually with the intent for the agent to act on behalf of the principal.

principal (debt) The amount of debt a borrower owes to a lender.

priority of claims in liquidation Established in Chapter 7 of the Bankruptcy Act. It specifies the order in which the debtor's assets are distributed among the creditors.

private equity (PE) fund Raises money from institutional investors and a relatively small number of high net-worth individuals. Private equity funds primarily invest in stock of private companies.

private placement The sale of stock to only one or a few investors, usually institutional investors. The advantages of private placements are lower flotation costs and greater speed, since the shares issued are not subject to Securities and Exchange Commission registration.

private markets Markets in which transactions are worked out directly between two parties and structured in any manner that appeals to them. Bank loans and private placements of debt with insurance companies are examples of private market transactions.

private placement of public equity (PIPE) When a public company sells shares of its stock directly to an investor, such as an insurance company or a pension fund.

pro forma financial statement Shows how a future statement would look if certain assumptions are realized. Also called a projected financial statement.

probability distribution (continuous) Probability distribution having an infinite number of possible outcomes. Often shown as a graph with outcomes on the x-axis having values that might range from $-\infty$ to

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

+∞ (although many probability distributions do not have an infinite range of possible outcomes). The values on the y-axis are a continuous curve that begin with a value of zero (or tangent to zero), are always positive, and end with a value of zero (or tangent to zero). Also, the area under this curve must be equal to 100% (this is a probability density function). Sometimes shown with cumulative probabilities on the y-axis (i.e., the probability that an outcome will be less than or equal to the value on the x-axis; this is a cumulative density function).

probability distribution (discrete) Probability distribution having a finite number of outcomes. Often presented as a listing, chart, or graph showing all possible outcomes with a probability assigned to each outcome. This listing of outcomes and probabilities is a probability density function.

professional association (PA) Participants are not relieved of professional (malpractice) liability, but have most of the benefits of incorporation.

professional corporation (PC) Has most of the benefits of incorporation but the participants are not relieved of professional (malpractice) liability.

profit margin Calculated by dividing net income by sales; gives the profit per dollar of sales. Also called the net profit margin or the profit margin on sales. Often denoted by M for margin.

profit margin on sales Calculated by dividing net income by sales; gives the profit per dollar of sales. Also called the net profit margin or just the profit margin. Often denoted by M for margin.

profit sharing plan Under this type of pension plan, employers make payments into the retirement fund but the payments to retirees vary with the level of corporate profits.

profitability index Found by dividing the project's present value of future cash flows by its initial cost. A profitability index greater than 1 is equivalent to a project's having positive net present value.

profitability ratios Ratios that show the combined effects of liquidity, asset management, and debt on operations.

progressive tax A tax system in which the higher one's income, the larger the percentage paid in taxes.

project cost of capital (r) The rate used to discount a project's cash flows after taking into consideration firm's overall cost of capital, the divisional cost of capital, and any additional subjective risk assessments for the particular project, including its impact on the firm's debt capacity. Also called the hurdle rate and the risk-adjusted cost of capital.

project cash flows The incremental cash flows of a proposed project. Equal to the cash flows of the company with the project minus the cash flows without the project.

project financing Financing method in which the project's creditors do not have full recourse against the borrowers; the lenders and lessors must be paid from the project's cash flows and equity.

promissory note A document specifying the terms and conditions of a loan, including the amount, interest rate, and repayment schedule. It is signed by the borrower when the bank approves the loan request.

proprietorship A business owned by one individual.

prospectus Summarizes information about a new security issue and the issuing company. Is part of the S-1 registration statement.

proxy A document giving one person the authority to act for another, typically the power to vote shares of common stock.

proxy fight An attempt to take over a company in which an outside group solicits existing shareholders' proxies, which are authorizations to vote shares in a shareholders' meeting, in an effort to overthrow management and take control of the business.

public markets Markets in which standardized contracts are traded on organized exchanges. Securities that are issued in public markets, such as common stock and corporate bonds, are ultimately held by a large number of individuals.

public offering An offer of new common stock to the general public.

publicly owned corporation Corporation in which the stock is owned by a large number of investors, most of whom are not active in management.

purchase accounting A method of accounting for a merger in which the merger is handled as a purchase. In this method, the acquiring firm is assumed to have

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

"bought" the acquired company in much the same way it would buy any capital asset.

purchasing power bond The interest rate of such a bond is based on an inflation index such as the consumer price index (CPI), so the interest paid rises automatically when the inflation rate rises, thus protecting the bondholders against inflation. The final principal payment is also linked to inflation. Also called an index bond.

purchasing power parity Implies that the level of exchange rates adjusts so that identical goods have the same true cost in different countries. For example, if converting domestic currency into foreign currency and purchasing a foreign product should have the same cost as purchasing an identical domestic product. Sometimes referred to as the "law of one price."

pure expectations theory States that the slope of the yield curve depends on expectations about future inflation rates and interest rates. Thus, if the annual rate of inflation and future interest rates are expected to increase, then the yield curve will be upward sloping; the curve will be downward sloping if the annual rates are expected to decrease.

pure play method Method of estimating a divisional beta as the average of betas from other companies that compete only in the division's line of business.

put option Allows the holder to sell the asset at some predetermined price within a specified period of time.

put–call parity relationship States that the value of a portfolio consisting of a put option and a share of stock must equal the value of a portfolio consisting of a call option (with the same strike price and expiration date as the put option) and cash, where the amount of cash is equal to the present value of the strike price.

PV The value today of a payment (or series of payments) that will be received in the future. PV is also the beginning amount that will grow to some future value.

PVA_N The value today of a future stream of N equal payments at the end of each period (an ordinary annuity).

$PVIFA_{I,N}$ The present value interest factor for an ordinary annuity of N periodic payments discounted at I percent interest per period.

$PVIF_{I,N}$ The present value interest factor for a lump sum received N periods in the future discounted at I percent per period.

Q

quantity discount Reduction in unit price when a large number of units are purchased.

quick ratio Indicates the extent to which current liabilities are covered by the most liquid current assets; it is found by dividing current assets less inventories by current liabilities. It is also called the acid test ratio.

quiet period for IPO Begins when an IPO registration statement is made effective; lasts for 40 days after the stock begins trading. Its purpose is to create a level playing field for all investors by ensuring that they all have access to the same information.

quoted interest rate The annual rate of interest stated in a contract, quoted for a security, or reported by the press. It is also called the going interest rate, the market interest rate, and the nominal annual interest rate.

R

ρ (rho), correlation coefficient A standardized measure of how two random variables covary. A correlation coefficient (ρ) of +1.0 means that the two variables move up and down in perfect synchronization, whereas a coefficient of −1.0 means the variables always move in opposite directions. A correlation coefficient of zero suggests that the two variables are not related to one another; that is, they are independent.

$\bar{r}_{Avg}$, average return The average return from a sample periods of past actual returns.

r^*, real risk-free interest rate The rate that a hypothetical riskless security pays each moment if zero inflation were expected. The real risk-free rate is not constant—r^* changes over time depending on economic conditions.

rating (bond) Reflects the probability that a bond will go into default. Bonds rated AAA have the least probability of defaulting.

r_d, required rate of return on debt The rate of return that fairly compensates an investor for purchasing or holding debt, taking into consideration its risk, timing, and the returns available on other similar investments. When referring to debt, r_d is also called the yield, the quoted market interest rate, the going rate, and the nominal interest rate.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

real options Occur when managers can influence the size and risk of a project's cash flows by taking different actions during the project's life. They are referred to as real options because they deal with real as opposed to financial assets. They are also called managerial options because they give opportunities to managers to respond to changing market conditions. Sometimes they are called strategic options because they often deal with strategic issues. Finally, they are also called embedded options because they are a part of another project.

real rate of return (r_r) Return that reflects actual growth in future purchasing power when there is inflation. For example, suppose you invest $100 now and receive $110 in 1 year. The nominal rate of return is 10%. If inflation has caused price to go up by 10%, then your investment will not provide any additional purchasing power relative to the amount that your initial $100 could have purchased. Therefore, the investment's real rate of return is zero. In the context of project analysis, if net cash flows from a project do not include increases due to expected future inflation, then the cash flows should be discounted at the real cost of capital to estimate NPV and the internal rate of return resulting should be compared with the real cost of capital.

real risk-free interest rate (r*) The rate that a hypothetical riskless security pays each moment if zero inflation were expected. The real risk-free rate is not constant—r* changes over time depending on economic conditions.

realized rate of return on stock $(\bar{r}_{s)}$ The rate of return that was actually realized on a share of stock during a particular holding period. Also called the actual rate of return.

realized rate of return $(\bar{r}_t)$ The actual return an investor receives on his or her investment during period t. It can be quite different than the expected return.

receivables conversion period The average length of time required to convert a firm's receivables into cash. It is calculated by dividing accounts receivable by sales per day. Also called the average collection period or the days sales outstanding.

red herring A preliminary prospectus that may be distributed to potential buyers prior to approval of the registration statement by the Securities and Exchange Commission. After the registration has become effective, the securities—accompanied by the prospectus—may be offered for sale. Called a red herring because it is marked in red.

red line method Determines the reorder times for inventory items stocked in a bin by drawing a red line inside of the bin at the level of the reorder point. The inventory manager places an order when the red line shows.

redeemable at par Gives investors the right to sell the bonds back to the corporation at a price that is usually close to the par value. If interest rates rise, then investors can redeem the bonds and reinvest at the higher rates.

refunding operation Occurs when a company issues debt at current low rates and uses the proceeds to repurchase one of its existing high–coupon rate debt issues. Often these are callable issues, which means the company can purchase the debt at a call price lower than the market price.

registered stock exchange A trading venue that is registered as a stock exchange with the SEC. Must display quotes as well as report transactions.

registration statement (S-1) Required by the Securities and Exchange Commission before a company's securities can be offered to the public. This statement is used to summarize various financial and legal information about the company.

regular interest The situation when interest is not compounded; that is, interest is earned (or charged) only on principal and not on interest. Also called simple interest. Divide the nominal interest rate by 365 and multiply by the number of days the funds are borrowed to find the interest for the term borrowed.

Regulation National Market System (Reg NMS) A set of rules designed by the SEC to protect investors and foster competition among exchanges and other trading venues. The order protection rule is intended to prevent an investor from buying or selling stock on one exchange when a better price is available on another exchange.

reinvestment rate risk Occurs when a short-term debt security must be "rolled over." If interest rates have fallen then the reinvestment of principal will be at

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

a lower rate, with correspondingly lower interest payments and ending value.

relative priority doctrine More flexible than absolute priority. Gives a more balanced consideration to all claimants in a bankruptcy reorganization than does the absolute priority doctrine.

relaxed policy (current assets) A policy under which excessive amounts of cash and inventories are carried, and under which sales are stimulated by a liberal credit policy, resulting in a high level of receivables.

relevant risk An asset's contribution to a well-diversified portfolio's risk.

reorder point The inventory level at which a new order is placed.

reorganization (in bankruptcy) Restricting a lender's debt terms so that a borrower's company can continue to operate if the company is more valuable as a going concern than if it were liquidated. Can be informal or formal (via Chapter 11 of the bankruptcy code). A formal court-approved reorganization must adhere to the standards of fairness and feasibility.

repatriation The cash flow, usually in the form of dividends or royalties, from the foreign branch or subsidiary to the parent company. These cash flows must be converted to the currency of the parent and thus are subject to future exchange rate changes. A foreign government may restrict the amount of cash that may be repatriated. In addition, the parent's country may impose additional taxes on repatriated profits if the parent country has a higher tax rate than the foreign country.

replacement chain (common life) approach A method of comparing mutually exclusive projects that have unequal lives. Each project is replicated so that they will both terminate in a common year. If projects with lives of 3 years and 5 years are being evaluated, then the 3-year project would be replicated 5 times and the 5-year project replicated 3 times; thus, both projects would terminate in 15 years.

replicating portfolio A portfolio of assets whose prices are known and whose future payoffs identical to the payoffs of another asset. Because the payoffs of the portfolio and other asset are identical, the values of the portfolio and the other asset must also be identical.

repurchase (stock) Occurs when a firm purchases its own stock that it had previously issued. These shares of stock are then referred to as treasury stock.

required rate of return The rate of return that fairly compensates an investor for purchasing or holding a particular investment after considering its risk, timing, and the returns available on other similar investments. An investor requires the prospect of this return before investing.

required rate of return on a portfolio ($\mathbf{r_p}$) The minimum acceptable rate of return on a portfolio, considering both its risk and the returns available on other investments. With the Capital Asset Pricing Model, the required rate of return is equal to the risk-free rate plus the extra return (i.e., the risk premium) needed to induce an investor to hold the portfolio. The required rate of return on a portfolio is the weighted average of the required rates of returns of the stocks comprising the portfolio.

required rate of return on debt ($\mathbf{r_d}$) The rate of return that fairly compensates an investor for purchasing or holding debt, taking into consideration its risk, timing, and the returns available on other similar investments. When referring to debt, r_d is also called the yield, the quoted market interest rate, the going rate, and the nominal interest rate.

required rate of return on Stock i ($\mathbf{r_i}$) The minimum acceptable rate of return on Stock i, considering both its risk and the returns available on other investments. With the Capital Asset Pricing Model, the required rate of return is equal to the risk-free rate plus the extra return (i.e., the risk premium) needed to induce an investor to hold the stock.

required rate of return on stock ($\mathbf{r_s}$) Rate that shareholders require to be fairly compensated for the risk they bear. Also equal to the cost of common stock because it is the cost a company incurs to provide the required rate of return.

reserve borrowing capacity Exists when a firm uses less debt under "normal" conditions than called for by the trade-off theory, giving it the flexibility to use debt in the future when additional capital is needed. This avoids a negative signal caused by investors assuming that managers have more complete information and will issue stock when it is overvalued.

residual distribution model In this model, firms should pay dividends only when more earnings are available than needed to support the optimal capital budget.

residual value The market value of the leased property at the expiration of the lease. The estimate of

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

the residual value is one of the key elements in lease analysis.

restricted charitable contributions Donations that can be used only for designated purposes.

restricted policy (current assets) A policy under which current assets are minimized by reducing holdings of cash, short-term investments, inventories, and receivables.

restricted voting rights A provision that automatically deprives a shareholder of voting rights if the shareholder owns more than a specified amount of stock.

restrictive covenant Provisions in a bond indenture that cover such points as the conditions under which the issuer can pay off the bonds prior to maturity, the levels at which certain ratios must be maintained if the company is to issue additional debt, and restrictions against the payment of dividends unless earnings meet certain specifications. Also called a bond covenant or a covenant.

restructuring (of debt terms) Changing the terms of debt in an informal reorganization to avoid formal bankruptcy. Usually involves: (1) extending the time until the interest and/or principal payments are due; and (2) reducing the composition of the terms by reducing the interest and/or principal payments.

retained earnings The portion of the firm's earnings that have been saved rather than paid out as dividends.

retention growth equation Shows how growth is related to reinvestment and is expressed as follows: $g = ROE(Retentionratio)$.

retention ratio Percentage of net income retained; i.e., the percent *not* paid as a cash dividend.

retiree health benefits A major issue for employers because of the escalating costs of health care and a FASB ruling forcing companies to accrue the retiree health care liability rather than expensing the cash flows as they occur.

return on assets (ROA) Found by dividing net income by total assets; also called the return on total assets. Measures how much net income is generated per dollar of assets.

return on common equity (ROE) Found by dividing net income by common equity; also called return on equity. Measures shareholders' rate of return after incorporating the impact of financial leverage.

return on equity (ROE) Found by dividing net income by common equity; also called return on common equity. Measures shareholders' rate of return after incorporating the impact of financial leverage.

return on invested capital (ROIC) Net operating profit after taxes divided by total net operating capital. Provides a measure of how well the company is operating because it excludes the impact of financial leverage.

return on total assets (ROA) Found by dividing net income by total assets; also called the return on assets. Measures how much net income is generated per dollar of assets.

revaluation Occurs when the relative price of a currency is increased. It is the opposite of devaluation.

revenue bonds Type of municipal bonds that are secured by the revenues derived from projects such as roads and bridges, airports, water and sewage systems, and not-for-profit health care facilities.

reverse split Situation in which shareholders exchange a particular number of shares of stock for a smaller number of new shares.

revolving credit agreement A formal, committed line of credit extended by a bank or other lending institution. Borrower often must pay a commitment fee even if borrower doesn't draw on the line of credit.

r_i, required rate of return on Stock i The minimum acceptable rate of return on Stock i, considering both its risk and the returns available on other investments. With the Capital Asset Pricing Model, the required rate of return is equal to the risk-free rate plus the extra return (i.e., the risk premium) needed to induce an investor to hold the stock.

rights offering Occurs when a corporation sells a new issue of common stock to its existing stockholders. Each stockholder receives a certificate, called a stock purchase right, giving the stockholder the option to purchase a specified number of the new shares. The rights are issued in proportion to the amount of stock that each shareholder currently owns. Also called a preemptive rights offering.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

risk Exposure to the chance of an unfavorable event.

risk arbitrage The practice of purchasing stock in companies (in the context of mergers) that may become takeover targets.

risk premium The additional expected return on a higher risk investment relative to a lower risk investment. A higher expected return is required by investors as compensation for bearing higher risk.

risk premium for individual Stock i (RP_i) Product of the stock's beta and the market risk premium: $RP_i = b_i(RP_M)$.

risk aversion A risk-averse investor dislikes risk and requires a higher rate of return as an inducement to buy riskier securities.

risk-adjusted cost of capital (r) The rate used to discount a project's cash flows after taking into consideration firm's overall cost of capital, the divisional cost of capital, and any additional subjective risk assessments for the particular project, including its impact on the firm's debt capacity. Also called the project cost of capital and the hurdle rate.

risk-free interest rate (the nominal long-term rate) The quoted interest rate on a long-term U.S. Treasury bond, which is default-free, very liquid, and has a long time until maturity. It is exposed to inflation risk. It is also exposed to price volatility caused by interest rate volatility. The quoted risk-free rate of interest on a short-term U.S. Treasury bond, which is default-free and very liquid. Note that r_{T-bond} includes the premium for expected inflation and interest rate volatility related to maturity: $r_{T-bond} = r^* + IP + MRP$.

risk-free interest rate (the nominal short-term rate) The quoted risk-free rate of interest rate on a short-term U.S. Treasury bill, which is default-free, very liquid, and has a short time until maturity. Includes the premium for expected inflation and is approximated by $r_{T-bill} = r^* + IP$ It is exposed to inflation risk.

risk-free nominal rate of interest rate (r_{RF}) The quoted interest rate on a U.S. Treasury security, which is default-free and very liquid. In the context of short-term securities, the risk-free rate refers to a U.S. Treasury bill, which is default-free, very liquid, and has a short time until maturity (although it still is exposed to inflation risk). In the context of long-term securities, the risk-free rate refers to a U.S. Treasury bond, which is default-free, very liquid, and has a long time until maturity (although it still is exposed to inflation risk and price volatility caused by interest rate volatility).

risk-neutral valuation Method of derivative valuation that replaces the actual growth rates of asset values with the risk-free rate and then discounts the resulting cash flows at the risk-free rate. The result is the correct value of the asset (in the sense that there will be no arbitrage opportunities if asset is priced with the result of the risk-neutral valuation technique).

risky event An uncertain outcome that adversely affects a company's objectives.

roadshow Before an IPO, the senior management team and the investment banker make presentations to potential investors. They make three to five presentations daily over a 2-week period in 10 to 20 cities.

$\hat{r}_p$, expected rate of return on a portfolio The rate of return expected on a portfolio given its current price and expected future cash flows.

r_p, required rate of return on a portfolio The minimum acceptable rate of return on a portfolio, considering both its risk and the returns available on other investments. With the Capital Asset Pricing Model, the required rate of return is equal to the risk-free rate plus the extra return (i.e., the risk premium) needed to induce an investor to hold the portfolio. The required rate of return on a portfolio is the weighted average of the required rates of returns of the stocks comprising the portfolio.

RP_i, risk premium for individual Stock i Product of the stock's beta and the market risk premium: $RP_i = b_i(RP_M)$.

RP_M, market risk premium The difference between the expected return on the market and the risk-free rate. This is the extra rate of return that investors require to invest in the stock market rather than purchase risk-free securities. It is also called the equity premium or the equity risk premium.

r_r, real rate of return Return that reflects actual growth in future purchasing power when there is inflation. For example, suppose you invest $100 now and receive $110 in 1 year. The nominal rate of return is 10%.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

If inflation has caused price to go up by 10%, then your investment will not provide any additional purchasing power relative to the amount that your initial $100 could have purchased. Therefore, the investment's real rate of return is zero. In the context of project analysis, if net cash flows from a project do not include increases due to expected future inflation, then the cash flows should be discounted at the real cost of capital to estimate NPV and the internal rate of return resulting should be compared with the real cost of capital.

r_{RF}, risk-free nominal interest rate of interest The quoted interest rate on a U.S. Treasury security, which is default-free and very liquid. In the context of short-term securities, the risk-free rate refers to a U.S. Treasury bill, which is default-free, very liquid, and has a short time until maturity (although it still is exposed to inflation risk). In the context of long-term securities, the risk-free rate refers to a U.S. Treasury bond, which is default-free, very liquid, and has a long time until maturity (although it still is exposed to inflation risk and price volatility caused by interest rate volatility).

r_s, required rate of return on stock Rate that shareholders require to be fairly compensated for the risk they bear. Also equal to the cost of common stock because it is the cost a company incurs to provide the required rate of return.

$\bar{r}_s$, realized rate of return on stock The rate of return that was actually realized on a share of stock during a particular holding period.

$\hat{r}_s$, expected rate of return The rate of return expected on a stock given its current price and expected future cash flows. If the stock is in equilibrium, the required rate of return will equal the expected rate of return.

$\bar{r}_t$, realized rate of return The actual return an investor receives on his or her investment during period t. It can be quite different than the expected return.

Rule of 78 Method of allocating a payment's portions of interest and principal. The portion due to interest for a payment is defined as the number of remaining payments (not including the current payment) divided by the sum of the payment numbers. For example, with 12 payments, the sum of 1 through 12 is 78 and the interest allocation in the first payment is 12/78.

S

S corporation A small corporation that, under Subchapter S of the Internal Revenue Code, elects to be taxed as a proprietorship or a partnership yet retains limited liability and other benefits of the corporate form of organization.

safety stock (inventory) Inventory held to guard against larger-than-normal sales and/or shipping delays.

sale-and-leaseback A type of financial lease in which the firm owning the property sells it to another firm, often a financial institution, while simultaneously entering into an agreement to lease the property back from the firm.

salvage value The market value at which a used asset can be sold.

savings and loan association (S&L) A financial institution that takes in most of its deposits from members of their community and makes most if its loans to homeowners and consumers.

scenario analysis Assumes several possible scenarios, including the inputs and the probability of occurrence for each scenario. Uses the scenario's inputs to calculate key results (such as NPV), and then uses the probabilities to estimate the expected value and standard deviation of each key result.

seasonal effects on ratios Seasonal factors can distort ratio analysis. At certain times of the year, a firm may have excessive inventories in preparation of a "season" of high demand. Therefore, an inventory turnover ratio taken at this time will be radically different than one taken after the season.

seasoned equity offering The sale of additional shares of stock by a public company after its initial public offering.

seasoned bond Describes a bond that has not been issued within the past month or two. Such bonds usually are not actively traded because they often are held in portfolios until maturity.

secondary market Markets in which securities are resold after initial issue in the primary market. The New York Stock Exchange is an example.

secured basis loan A loan backed by collateral, which is often in the form of inventories or receivables.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

secured debt Debt for which a corporation pledges certain assets as security.

Securities and Exchange Commission (SEC) A government agency that regulates the sales of new securities and the operations of securities exchanges. The SEC, along with other government agencies and self-regulation, helps ensure stable markets, sound brokerage firms, and the absence of stock manipulation.

securitization The process whereby financial instruments that were previously thinly traded are converted to a form that creates greater liquidity. Securitization also applies to the situation where specific assets are pledged as collateral for securities, thus creating asset-backed securities. One example of the former is junk bonds; an example of the latter is mortgage-backed securities.

Security Market Line (SML) Represents, in a graphical form, the relationship between the risk of an asset as measured by its beta and the required rates of return for individual securities. The SML equation is one of the key results of the CAPM: $r_i = r_{RF} + b_i(r_M - r_{RF}) = r_{RF} + b_i(RP_M)$.

self-liquidating approach (for short-term financing) A policy that matches asset and liability maturities. It is also referred to as the maturity matching approach.

selling group All members of an underwriting syndicate plus additional dealers usually selling to retail customers.

semiannual compounding When interest is compounded twice per year.

semistrong form of market efficiency States that current market prices reflect all publicly available information. Therefore, the only way to gain abnormal returns on a stock is to possess inside information about the company's stock.

sensitivity analysis Indicates exactly how much net present value will change in response to a given change in an input variable, other things held constant. Sensitivity analysis is sometimes called "what if" analysis because it answers this type of question.

settlement (payment process) Occurs when the payer's bank actually deducts the payment amount from the account balance and the payee's bank actually deposits the amount into the payees account.

shareholder rights provision Allows existing shareholders in a company to purchase additional shares of stock at a lower-than-market value if a potential acquirer purchases a controlling stake in the company. Also called a poison pill.

Sharpe's reward-to-variability ratio Asset's average return (in excess of the risk-free rate) divided by its standard deviation. Measure the return per unit of risk as defined by standard deviation.

shelf registration Frequently, companies will file a master registration statement and then update it with a short form statement just before an offering. This procedure is termed *shelf registration* because companies put new securities "on the shelf" and then later sell them when cash is needed and market conditions are favorable.

short hedges Obligates the party to sell the underlying asset at a predetermined price, providing protection against price decreases. For example, a farming company might go short in wheat to protect itself from decreases in wheat prices.

signaling hypothesis (dividends) A theory that holds that investors regard dividend changes as "signals" of management forecasts. Thus, when dividends are raised, this is viewed by investors as recognition by management of future earnings increases. Therefore, if a firm's stock price increases with a dividend increase, the reason may not be investor preference for dividends but rather expectations of higher future earnings. Conversely, a dividend reduction may signal that management is forecasting poor earnings in the future. Also called the dividend information content hypothesis.

signaling theory (capital structure) Assumes managers have more complete information than investors and will issue stock when it is overvalued, causing a stock issue to be a negative signal. Leads to a preferred "pecking order" of financing: (1) retained earnings, followed by (2) debt, and then (3) new common stock. Also known as the capital structure asymmetric information theory.

simple interest The situation when interest is not compounded; that is, interest is earned (or charged) only on principal and not on interest. Also called regular interest. Divide the nominal interest rate by 365 and multiply by the number of days the funds are borrowed to find the interest for the term borrowed.

Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

simulation analysis A risk analysis technique in which a computer is used to simulate probable future events and thus to estimate the likely profitability and risk of a project. Often called Monte Carlo simulation analysis.

sinking fund Facilitates the orderly retirement of a bond issue. This can be achieved in one of two ways: (1) The company can call in for redemption (at par value) a certain percentage of bonds each year. (2) The company may buy the required amount of bonds on the open market.

social value Projects of not-for-profit businesses are expected to provide a social value in addition to an economic value.

soft currency A currency that cannot be traded freely in the international currency markets and cannot be exchanged at current market rates but must be exchanged at a rate set by the country's government. Often called a nonconvertible currency.

special dividend A dividend paid, in addition to the regular dividend, when earnings permit. Firms with volatile earnings may have a low regular dividend that can be maintained even in years of low profit (or high capital investment) but is supplemented by an extra dividend when excess funds are available.

special purpose entity (SPE) Created when a company establishes a separate legal entity but provides a guarantee of the entity's liabilities. This guarantee allows the entity to borrow money and then purchase financial or physical assets. Because the entity is separate from the creating company, the entity's assets and liabilities are reported on its own balance sheets and not those of the creating company. The entity usually has a narrow purpose, such as purchasing an asset and leasing it to the creating company.

special tax bonds Type of municipal bonds that are secured by a specified tax, such as a tax on utility services.

specific identification Inventory accounting method in which a unique cost is attached to each item in inventory. When an item is sold, the inventory value is reduced by that specific amount.

speculation in derivatives Occurs when one of the counterparties is not hedging away risk but is instead entering the derivatives contract in the hopes of making a profit on the contract.

speculative balances Funds held by a firm in order to have cash for taking advantage of bargain purchases or growth opportunities.

spin-off Occurs when a holding company distributes the stock of one of the operating companies to its shareholders, thus passing control from the holding company to the shareholders directly.

spin-out IPO in which a parent company creates a new publicly traded company from a subsidiary and sells some of the stock to the public. Parent companies typically retain at least 80% of the subsidiary's common stock to maintain control and to preserve their ability to file a consolidated tax return. Also called a partial public offering or an equity carve-out.

spontaneous liabilities Liabilities that grow with sales, such as accounts payable and accruals.

spontaneous liabilities-to-sales ratio $(\mathbf{L_0^*/S_0})$ The ratio of spontaneous liabilities at Time 0 (L_0) divided by the sales at Time 0 (S_0). This is the amount of spontaneous liabilities generated by a dollar of sales, which reduces the need for external financing to support sales.

spot markets Where assets are bought or sold for "on-the-spot" delivery (literally, within a few days).

spot rate (foreign exchange) Specifies the number of units of a given currency that can be purchased for one unit of another currency for immediate (on the spot) delivery.

spread (bond yield) The difference between the yield of a bond relative to another bond with less risk.

spread, underwriting The difference between the offer price at which an underwriter sells the stock in an initial public offering and the proceeds that the underwriter passes on to the issuing firm; the fee collected by the underwriter. It is often about 7% of the offering price.

stakeholders All parties that have an interest, financial or otherwise, in a company. This includes employees and the communities in which the company does business.

stand-alone risk The risk an investor would take by holding only one asset. In the context of project analysis, it is the risk a company would have if the company had only one project and it is caused by

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

variability in a project's cash flows. The standard deviation is used often to measure stand-alone risk.

standard deviation, σ A statistical measure of how dispersed a set of observations are about the mean of the observations. It is the square root of the variance.

statement of cash flows Reports the impact of a firm's operating, investing, and financing activities on cash flows over an accounting period.

statement of stockholders' equity Statement showing the beginning stockholders' equity, any changes due to stock issues/repurchases, the amount of net income that is retained, and the ending stockholders' equity.

stepped-up strike (or exercise) price A provision in a warrant that increases the strike price over time. This provision is included to encourage owners to exercise their warrants.

stock dividend Increases the number of shares outstanding but at a slower rate than splits. Current shareholders receive additional shares on some proportional basis. Thus, a holder of 100 shares would receive 5 additional shares at no cost if a 5% stock dividend were declared.

stock exchange (registered) A trading venue that is registered as a stock exchange with the SEC. Must display quotes as well as report transactions.

stock option A contract that gives its holder the right to buy or sell a share of stock at some predetermined price within a specified period of time. For example, a call option on a stock allows the option's owner to purchase a share of stock at a fixed price, called the strike price or the exercise price, no matter what the actual price of the stock is. Stock options always have an expiration date, after which they cannot be exercised.

stock option compensation plan An additional form of employee compensation above and beyond cash salaries and cash bonuses in which the employee is granted call options on the firm's stock. Typical plans do not vest immediately but require that the employee stay with the company a specified period before exercising the option is permitted.

stock repurchase Occurs when a firm purchases its own stock that it had previously issued. These shares of stock are then referred to as treasury stock.

stock split Current shareholders are given some number (or fraction) of shares for each stock share owned. Thus, in a 3-for-1 split, each shareholder would receive three new shares in exchange for each old share, thereby tripling the number of shares outstanding. Stock splits usually occur when the stock price is outside of the optimal trading range.

stock-out cost (inventory) The cost of running short of inventory and subsequently losing sales.

straight-line depreciation method Depreciation method for financial reporting purposes that calculates depreciation basis as the acquisition cost minus the expected salvage and then divides the basis by the number of years until salvage to determine the annual depreciation rate that can be applied to the basis.

strategic alliance A cooperative deal that stops short of a merger but still allows firms to create combinations that focus on specific business lines that offer the most potential synergies. Also called a corporate alliance.

strategic options Options that often deal with strategic issues. Also called real options, embedded options, and managerial options.

stretching accounts payable The practice of deliberately paying accounts late.

strike (or exercise) price The price stated in the option contract at which the security can be bought (or sold).

strong form of market efficiency Assumes that all information pertaining to a stock, whether public or inside information, is reflected in current market prices. Thus, no investors would be able to earn abnormal returns in the stock market.

structured note A debt obligation derived from another debt obligation. Permits a partitioning of risks to give investors what they want.

subordinated debenture Debentures that have claims on assets, in the event of bankruptcy, only after senior debt (as named in the subordinated debt's indenture) has been paid off. Subordinated debentures may be subordinated to designated notes payable or to all other debt.

subsidiary A company whose stock is owned by other companies. If all the stock is owned by one company, it is called a wholly owned subsidiary.

sunk cost A cost that has already occurred and is not affected by the capital project decision. Sunk costs are not relevant to capital budgeting decisions.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

super poison put Enables a bondholder to turn in, or "put," a bond back to the issuer at par in the event of a takeover, merger, or major recapitalization.

supply chain The network of organizations that convert materials and labor into products or services that ultimately are purchased by consumers.

swap An exchange of cash payment obligations. Usually occurs because the parties involved prefer someone else's payment pattern or type.

sweetener A feature that makes a security more attractive to some investors, thereby inducing them to accept a lower current yield. Convertible features and warrants are examples of sweeteners.

symmetric hedge Occurs for a derivative in which the payoff from a dollar increase in the underlying asset has exactly the opposite effect of a dollar decrease in the underlying asset. For example, forward contracts and futures have symmetric payoffs.

symmetric information When investors have the same information as managers.

synchronization of cash flows Occurs when firms are able to time cash receipts to coincide with cash requirements.

synergistic benefits Difference between the value of a company to an acquirer (which reflects synergy) and the value to the target if not acquired.

synergy Occurs when the whole is greater than the sum of its parts. When applied to mergers, a synergistic merger occurs when the post-merger earnings exceed the sum of the separate companies' pre-merger earnings.

synthetic lease Version of an operating lease in which a company established a special-purpose entity to borrow funds in the financial markets, purchase an asset with the borrowed funds, and then lease the asset to the creating company.

T

takeover An action whereby a person or group succeeds in ousting a firm's management and taking control of the company.

tapping fund assets Deals with the issue of allowing a corporation to invest its pension fund assets to the corporation's own advantage.

target capital structure Percentages of the different sources of capital the firm plans to use on a regular basis, with the percentages based on the market values of those sources. These percentages are used to estimate the weighted average cost of capital.

target cash balance The desired cash balance that a firm plans to maintain in order to conduct business.

target company A firm that another company seeks to acquire.

target distribution ratio Percentage of net income distributed to shareholders through cash dividends or stock repurchases. The actual distribution ratio can vary from the target year to year, but the average actual distribution ratio over time should match the target.

target payout ratio Percentage of net income that company seeks to pay as a cash dividend. The actual payout ratio can vary from the target year to year, but the average actual payout ratio over time should match the target.

target stock or tracking stock A class of stock with dividends tied to a particular part of a company. Also called tracking stock.

targeted share repurchases Also known as greenmail, occurs when a company buys back stock from a potential acquirer at a price that is higher than the market price. In return, the potential acquirer agrees not to attempt to take over the company.

tax effect theory Proposes that investors prefer capital gains over dividends, because capital gains taxes can be deferred into the future but taxes on dividends must be paid as the dividends are received.

tax loss carryback and carryforward Ordinary corporate operating losses can be carried backward for 2 years or forward for 20 years to offset taxable income in a given year.

tax savings due to interest (TS_t) Tax savings in year t due to the deductibility of interest expenses. Also called the annual tax shield.

taxable income Gross income less a set of exemptions and deductions that are spelled out in the instructions to the tax forms that individuals must file.

tax-exempt bonds Bonds issued by industrial development agencies and pollution control agencies whose proceeds are made available to corporations for uses deemed

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

(by Congress) to be in the public interest. The interest paid to investors is exempt from federal income taxes.

tax-oriented lease Meets all of the Internal Revenue Service (IRS) requirements for a genuine lease. If a lease meets the IRS guidelines, the IRS allows the lessor to deduct the asset's depreciation and allows the lessee to deduct the lease payments. Also called a guideline lease.

T-bill A Treasury bill, which is a short-term security issued by the federal government. A T-bill has a maturity of 52 weeks or less at the time of issue, and it makes no payments at all until it matures. Thus, T-bills are sold initially at a discount to their face, or maturity, value. T-bills have no default risk.

T-bond Treasury bonds issued by the federal government. A T-bond makes an equal payment every 6 months until it matures, at which time it makes an additional lump-sum payment of its par value. If the maturity at the time of issue is less than 10 years, the security is called a note rather than a bond. T-bonds have no default risk.

technical analysts Stock analysts who believe that past trends or patterns in stock prices can be used to predict future stock prices.

TED spread The 3-month LIBOR rate minus the 3-month T-bill rate. It is a measure of risk aversion and measures the extra compensation that banks require to induce them to lend to one another.

temporary net operating working capital The NOWC required above the permanent level when the economy is strong and/or seasonal sales are high.

temporary operating current assets The operating current assets required above the permanent level when the economy is strong and/or seasonal sales are high.

tender offer The offer of one firm to buy the stock of another by going directly to the stockholders, frequently over the opposition of the target company's management.

term structure of interest rates The relationship between yield to maturity and term to maturity for bonds of a single risk class.

terminal date The last year in a cash flow forecast. Cash flows may grow unevenly during the forecast period, but are assumed to grow at a constant rate for all periods after the terminal date. Also called the forecast horizon or the horizon date.

terminal value The present value of all free cash flows beyond the horizon date discounted back to the horizon date. Also called the horizon value (because it is at the horizon date) or the continuing value (because it is the value if operations continue to be used rather than be liquidated).

time line A graphical representation used to show the timing of cash flows.

time value of an option The difference between an option's price and its exercise value.

time value of money (TVM) analysis The method of determining today's value of a cash flow to be received in the future. Also called discounted cash flow analysis.

times-interest-earned (TIE) ratio Determined by dividing earnings before interest and taxes by the interest charges. This ratio measures the extent to which operating income can decline before the firm is unable to meet its annual interest costs.

tornado diagram A chart resembling a tornado because it shows the results of a sensitivity analysis with the range in possible outcomes for each variable drawn as horizontal bars arranged from the widest bar (i.e., the range for the input to which the output is most sensitive) at the top and the smallest bar at the bottom.

total assets turnover ratio Measures the turnover of all the firm's assets; it is calculated by dividing sales by total assets.

total carrying cost (TCC) The costs of carrying inventory.

total inventory costs (TIC) The sum of ordering and carrying costs.

total net present value (TNPV) Equal to net present value plus net present social value in a not-for-profit business.

total ordering cost (TOC) The costs of ordering inventory.

tracking stock A class of stock with dividends tied to a particular part of a company. Also called target stock or targeting stock.

Copyright 2017 Cengage Learning. All Rights Reserved. May not be copied, scanned, or duplicated, in whole or in part. Due to electronic rights, some third party content may be suppressed from the eBook and/or eChapter(s). Editorial review has deemed that any suppressed content does not materially affect the overall learning experience. Cengage Learning reserves the right to remove additional content at any time if subsequent rights restrictions require it.

trade balance (deficit or surplus) Deficit occurs when a country imports more goods from abroad than it exports; surplus is the reverse and occurs when a country exports more than it imports.

trade credit Arising from credit sales and is the amount of the sale price that is not paid in cash at the time of the purchase; recorded as an account receivable by the seller and as an account payable by the buyer.

trade discounts A provision in credit terms: A percentage reduction in the sales price if the purchaser pays in cash before the end of the specified discount period. Otherwise, the full price is due at the end of the regular credit period. Also called "cash discounts" or just "discounts."

trade-off theory The addition of financial distress and agency costs to either the MM tax model or the Miller model. In this theory, the optimal capital structure can be visualized as a trade-off between the benefit of debt (the interest tax shelter) and the costs of debt (financial distress and agency costs).

trading venue A site (geographical or electronic) where secondary market trading occurs, including stock exchanges, alternative trading systems, and broker-dealer networks.

transactions balance The cash balance associated with payments and collections; the balance necessary for day-to-day operations.

transfer price Price a subsidiary pays a parent for raw materials, finished goods, or other goods and services.

transnational corporation A corporation that operates in an integrated fashion in more than one country. Also called global corporation, multinational corporation, and multinational enterprise.

Treasury bill (T-bill) A short-term security issued by the federal government. A T-bill has a maturity of 52 weeks or less at the time of issue, and it makes no payments at all until it matures. Thus, T-bills are sold initially at a discount to their face, or maturity, value. T-bills have no default risk.

Treasury bond (T-bond) Bonds issued by the federal government; sometimes called T-bonds or government bonds. A T-bond makes an equal payment every 6 months until it matures, at which time it makes an additional lump-sum payment of its par value. If the maturity at the time of issue is less than 10 years, the security is called a note rather than a bond. T-bonds have no default risk.

Treasury Inflation-Protected Security (TIPS) A bond issued by the U.S. government with a principal amount that is based on an inflation index such as the consumer price index (CPI). This causes interest rates and the final principal payment to automatically rise when the inflation rate rises, thus protecting the bondholders against inflation.

trend analysis An analysis of a firm's financial ratios over time. It is used to estimate the likelihood of improvement or deterioration in its financial situation.

Treynor's reward-to-volatility ratio Asset's average return (in excess of the risk-free rate) divided by its beta. Measure the return per unit of risk as defined by beta.

trustee (for bond indenture) Official (usually a bank) who represents the bondholders and makes sure the terms of the indenture are carried out.

trustee (in bankruptcy) Third party appointed by bankruptcy court to manage the company during the bankruptcy period; only happens if the court deems current management incompetent or if fraud is suspected.

two-bin method Determines the reorder times for inventory items stocked in two bins. When the working bin is empty, an order is placed and inventory is drawn from the second bin until the new inventory arrives.

U

uncollected balances schedule Reports each month's remaining receivables as a percentage of the month's sales. Adds together the monthly percentages for a given period, such as each quarter, and provides a comparison of this sum over time. Avoids misleading signals that are given by the DSO and aging schedule when sales are seasonal.

underfunded pension plan The present value of expected retirement benefits exceeds the assets on hand.

underinvestment problem A type of agency problem in which managers might forgo positive NPV projects unless they are extremely safe. Occurs because a bankruptcy or other failure damages the manager's reputation and potential future earnings. This problem is more severe for highly levered firms.

underwriter (of IPO) Investment bank that agrees to buy all stock in an initial public offering from issuing company at a set price and then resell the stock to investors at the offering price. Underwriter bears risk of selling the issue.

underwriting syndicate Group of investment banks that underwrites a security issuance; minimizes the risk each individual bank faces.

underwritten arrangement Contract between a firm and an investment banker when stock is issued. An investment banker agrees to buy the entire issue at a set price and then resells the stock at the offering price. Thus, the risk of selling the issue rests with the investment banker.

uneven cash flow stream A stream of cash flows that cannot be represented by an annuity.

unlevered beta The beta that a firm would have if it had no debt. Can be estimated using the Hamada equation: $b_U = b/[1 + (1-T)(D/S)] = b/[1 + (1-T)(w_d/w_s)]$

unsyndicated offering Offering in which the managing underwriter—acting alone—sells the issue entirely to a group of institutional investors.

V

value-based management Systematic use of the free cash flow valuation model to identify value drivers and to guide managerial and strategic decisions.

value of operations (V_{op}) The present value of all expected future free cash flows when discounted at the weighted average cost of capital.

value at risk (VaR) The dollar value that defines a specified percentile in the probability distribution of portfolio's loss or a project's NPV. For example, if the specified percentile is 5%, a VaR of –$1 million means that there is a 5% probability that the portfolio will lose $1 million or more.

value drivers Inputs to the free cash flow valuation model that managers are able to influence through strategic choices and execution of business plans. These include the revenue growth rate, the operating profitability ratio, the capital requirement ratio, and the weighted average cost of capital.

value of preferred stock (V_{ps}) The constant fixed dividend (D_{ps}) divided by the preferred stock's required rate of return (r_{ps}).

variance, σ^2 A measure of a distribution's variability. It is the sum of the squared deviations about the expected value.

venture capitalist The manager of a venture capital fund. The fund raises most of its capital from institutional investors and invests in start-up companies in exchange for equity.

venture capital fund Private limited partnership that typically raises cash from a relatively small group of primarily institutional investors and then purchases equity in start-up companies.

vertical merger Occurs when a company acquires another firm that is "upstream" or "downstream"; for example, an automobile manufacturer acquires a steel producer.

vesting If an employee has the right to receive pension benefits even if they leave the company prior to retirement, their rights are said to be vested.

vesting period Period during which employee stock options cannot be exercised.

Volcker rule A part of the Dodd-Frank Act named after former Fed chairman Paul Volcker. It seeks to limit a bank's proprietary trading, such as investing the banks' own funds into hedge funds.

voluntary petition (in bankruptcy) Filing by borrower of petition in bankruptcy court.

V_{ps}, value of preferred stock The constant fixed dividend (D_{ps}) divided by the preferred stock's required rate of return (r_{ps}).

W

warrant A call option, issued by a company, that allows the holder to buy a stated number of shares of stock from the company at a specified price. Warrants are generally distributed with debt, or preferred stock, to induce investors to buy those securities at lower cost.

weak form of market efficiency Assumes that all information contained in past price movements is fully reflected in current market prices. Thus, information about recent trends in a stock's price is of no use in selecting a stock.

weighted average cost of capital (WACC) The weighted average of the after-tax component costs of capital—debt, preferred stock, and common equity.

Each weighting factor is the proportion of that type of capital in the optimal, or target, capital structure.

weighted average inventory valuation method Determines the weighted average unit cost of goods available for sale from inventory based on past purchases and past usage of inventory.

white knight A friendly competing bidder that a target management likes better than the company making a hostile offer; the target solicits a merger with the white knight as a preferable alternative.

white squire An investor who is friendly to current management and can buy enough of the target firm's shares to block a merger.

window dressing Techniques employed by firms to make their financial statements look better than they really are.

within -firm risk The variability a project contributes to a corporation's returns; also called corporate risk.

working capital A firm's investment in short-term assets—cash, marketable securities, inventory, and accounts receivable.

workout Voluntary reorganization plans arranged between creditors and generally sound companies experiencing temporary financial difficulties. Workouts typically require some restructuring of the firm's debt.

writing an option The act of creating an option and then selling it to someone else. The writer of the option is obligated to honor its terms if the purchaser of the option decides to exercise the option. For example, the writer of a call option might receive \$4 from an investor for an option with a strike price of \$20. If the option expires out-of-the-money (the price at expiration is less than \$20), the writer has a \$4 profit. However, if the stock price is \$25 when the investor exercises the option, then the writer must sell a share of stock that is worth \$25 to the investor for the price of \$20. In this case, the writer would have received \$4 from writing the option but would have lost \$5 when it was exercised, for a net loss of \$1.

Y

Yankee bonds Bond issued by a foreign borrower denominated in dollars and sold in the United States under SEC regulations.

yield The rate of return that fairly compensates an investor for purchasing or holding debt, taking into consideration its risk, timing, and the returns available on other similar investments. It is also called the required rate of return on debt (r_d), the quoted market interest rate, the going rate, and the nominal interest rate.

yield curve The curve that results when yield to maturity is plotted on the y-axis with term to maturity on the x-axis.

yield to call (YTC) The rate of interest earned on a bond if it is called. If current interest rates are well below an outstanding callable bond's coupon rate, then the YTC may be a more relevant estimate of expected return than the YTM because the bond is likely to be called.

yield to maturity (YTM) The rate earned on a bond if it is held to maturity.

Z

zero coupon bond Pays no coupons at all but is offered at a substantial discount below its par value and hence provides capital appreciation rather than interest income.

zero working capital target Managerial objective to set: Inventories + Receivables−Payables = 0. Frees up cash, speeds up production, and helps businesses operate more efficiently.

Subject Index

In this index, *f* represents figure, *t* represents table, and n indicates entries that can be found in notes.

A

AAA bonds, 224
AAA-rated companies, 225
Abandonment, 1016
Abandonment options, 481
Abbott Labs, 225
ABB Swiss automation, 878
Abercrombie & Fitch, 552
AB InBev, 674
Abnormal yield curve, 227
Absolute priority doctrine, 956
Accelerated Cost Recovery System (ACRS), 498–500
Accelerated depreciation
  methods of, 498–500
  straight-line depreciation *v.*, 465–466
Accounting beta method, 400
Accounting cost, 82
Accounting profit, 64
Accounting rate of return, 442
Accounts payable (trade credit), 657, 674
Accounts receivable, 657
Accredited investors, 752
Accrual accounting, 61n1
Accruals, 673
Acid test ratio, 106
Acquiring company, 878
Actual after-the-fact rate of return, 321
Additional funds needed (AFN) equation method, 523–526
  addition to retained earnings, 523–524
  calculating, 524
  key factors in, 524–525
  required increase in assets, 523
  self-supporting growth rate, 526
  spontaneous liabilities, 523
  use MicroDrive data to implement, 524
Adjustable rate mortgage (ARM), 45, 179
Adjustable rate preferred stock (ARP), 822–823
Adjusted betas, 1002
Adjusted present value (APV) approach, 850–853
  beta, levered, 852–853
  corporate valuation and, 863–865
  equity, levered cost of, 852
  levered firm, value of, 850–852
  tax shield discount rate, 853
Adjustment bureau, 950
AerCap Holdings NV, 791
AFN. *See* Additional funds needed equation
After-tax cost of debt, 379–383, 834n13
  before-tax cost of long-term debt, 380
  before-tax cost of short-term debt, 379
  flotation/cost of debt, 382–383
  interest rate on debt, 381
Agency conflicts, 542–545
  inside owner/manager/outside owner, 544
  managers/shareholders, 544–545
  stockholder/creditor, 543
Agency costs, 542–543, 835–837
Agency debt, 195
Agency relationship, 542
Agent, 542
Aggressive approach, 661
Aging schedule, 672
AIG investments, 48, 550
Alcan Aluminum, 729
Alcoa, 16
Alibaba, 8, 729
Alternate Minimum Tax (AMT), 86, 573n11, 809
Alternative trading system (ATS), 38
Amazon.com, 3, 57, 667, 761
American Association of Individual Investors (AAII), 126
American Depository Receipts (ADRs), 729
American option, 345
American Recovery and Reinvestment Act of 2009, 49
Amgen-Onyx Pharmaceuticals, 877
Amortization, 63
Amortization schedule, 177
Amortized loans, 175–178
  amortization schedule, 177
  mortgage interest payments, 177–178
  payments, 176–177
Analysts' forecasts, 392
Anchoring bias, 280
Angel investors, 752
Anheuser-Busch InBev, 729
Annual compounding, 170–174
Annual dividend, 568
Annual financing choices, 394
Annual percentage rate (APR), 173
Annual report, 58–59
Annual Statement Studies (Risk Management Associates), 124
Annual unit sales, 459–460
Annual vesting, 549
Annuities, TVM and, 155–156
Annuity, 155
  future value of, 156–158
  growing, 178–181
  payments (PMT) finding, 162–163
  plus additional final payment, 166
  variable, 163
Annuity due, 156
  future value of, 159
  present value of, 161–162
Annuity plus a final lump sum, 169
Anti-bribery Convention, 727
